

# **Comparing Reductions to NP-Complete Sets**

John M. Hitchcock<sup>\*</sup>, A. Pavan<sup>†</sup>

#### Abstract

Under the assumption that NP does not have p-measure 0, we investigate reductions to NP-complete sets and prove the following:

- 1. Adaptive reductions are more powerful than nonadaptive reductions: there is a problem that is Turing-complete for NP but not truth-table-complete.
- 2. Strong nondeterministic reductions are more powerful than deterministic reductions: there is a problem that is SNP-complete for NP but not Turing-complete.
- 3. Every problem that is many-one complete for NP is complete under length-increasing reductions that are computed by polynomial-size circuits.

The first item solves one of Lutz and Mayordomo's "Twelve Problems in Resource-Bounded Measure" (1999). We also show that every problem that is complete for NE is complete under one-to-one, length-increasing reductions that are computed by polynomial-size circuits.

### 1 Introduction

A language  $L \in NP$  is NP-complete if every language in NP is *reducible* to L. There are several possible interpretations of the word "reducible." Polynomial-time many-one reducible is the most typical meaning, but there are many other reducibilities, each providing a potentially different NP-completeness notion. Are there languages that are NP-complete using one type of reduction but not complete under another type of reduction? Are there two apparently different notions of reductions for which the corresponding completeness notions coincide? We study these questions for several types of reductions.

#### 1.1 Adaptive versus Nonadaptive Reductions

A many-one reduction  $(\leq_{\mathrm{m}}^{\mathrm{p}})$  from A to B converts a question about membership in A to an equivalent question about membership in B. Formally, there is a function f such that  $x \in A$  if and only if  $f(x) \in B$ . A variation on this theme is to allow the use of B as an oracle to solve A. Here there is an algorithm M that takes as input an instance x of A and may ask multiple queries about instances of B before outputting its decision for x. There are two basic forms of this type of reduction: adaptive and nonadaptive. In an adaptive reduction (also called a Turing reduction,  $\leq_{\mathrm{T}}^{\mathrm{p}}$ ) M receives the answer for each query before asking its next query – subsequent queries may depend on the answers to previous queries. In a nonadaptive reduction (also called a truth-table reduction,  $\leq_{\mathrm{tt}}^{\mathrm{p}}$ ) M asks all of its queries before receiving any answers.

Lutz and Mayordomo [23] showed that if NP does not have p-measure zero (written  $\mu_p(NP) \neq 0$ ), then adaptive completeness for NP is different from many-one completeness. In fact, they showed this hypothesis yields a problem that is complete for NP under adaptive reductions that make only two queries, but is not complete under many-one reductions. In the conclusion of their paper, Lutz and Mayordomo conjectured that the measure hypothesis would yield separations of other completeness notions between  $\leq_{m}^{p}$  and  $\leq_{T}^{p}$  for NP, similar to what is known unconditionally for E and NE [29, 9].

Since then there have been several results in this direction. Ambos-Spies and Bentzien [5] used a genericity hypothesis on NP, an assumption which is implied by the measure hypothesis, to separate essentially all bounded-query completeness notions for NP. It is also known that some of these separations can be obtained under bi-immunity hypotheses [27, 18], which are even weaker assumptions. For a survey of these results see [25].

However, so far a separation of adaptive completeness from nonadaptive completeness for NP has been elusive. This question has been asked in several survey papers [11, 22, 12, 24], most prominently as one of Lutz and Mayordomo's "Twelve Problems in Resource-Bounded Measure," Problem 9:

Does  $\mu_p(NP) \neq 0$  imply the existence of a problem that is  $\leq_T^p$ -complete, but not  $\leq_{tt}^p$ -complete, for NP?

The only partial result on this problem was by Pavan and Selman [26] who used a strong hypothesis about UP to separate these two completeness notions. We affirmatively answer the above question. Our proof combines the connection between the measure of NP and the NP-machine hypothesis [17] with results about nonadaptive reductions to P-selective sets [10, 28].

#### **1.2** Nondetermistic versus Deterministic Reductions

Adleman and Manders [1] observed that while most problems can be shown to be NP-complete using polynomial-time reductions, some problems resist this approach. To classify such problems, they proposed what are now called *strong nondeterministic many-one reductions*. (Adleman and Manders called these reductions  $\gamma$ -reductions.) If a language that is NP-complete under strong nondeterministic reductions admits an efficient algorithm, then NP = coNP. Therefore, if we believe NP  $\neq$  coNP, strong nondeterministic completeness can also be taken as evidence that the problem in hand is intractable.

Adleman and Manders showed that some number-theoretic problems are NP-complete under strong nondeterministic many-one reductions. Chung and Ravikumar [13] showed that certain questions regarding comparator networks are also NP-complete under these reductions. It is not known whether these problems remain complete if we use polynomial-time reductions.

This situation raises the following question: are there languages that are complete under strong nondeterministic reductions, but not complete under polynomial-time reductions? We show that if  $\mu_{\rm p}(\rm NP) \neq 0$ , then the answer to this question is yes, even if we consider polynomial-time adaptive reductions.

#### **1.3 Length-Increasing Reductions**

It has been observed that many NP-completeness results hold under very restrictive reductions. For example, SAT is complete under polynomial-time reductions that are one-to-one and lengthincreasing. In fact, all known NP-complete problems are complete under this type of reduction [8]. This raises the following question: are there languages that are complete under polynomialtime many-one reductions but not under complete polynomial-time, one-to-one, length-increasing reductions?

Berman [7] showed that every many-one complete set for E is complete under one-to-one, length-increasing reductions. Thus for E, these two completeness notions coincide. A weaker result is known for NE. Ganesan and Homer [15] showed that all NE-complete sets are complete via one-to-one reductions that are exponentially honest.

For NP, until very recently there had not been any progress on this question. Agrawal [3] showed that if one-way permutations exist, then all NP-complete sets are complete via one-to-one, length-increasing, p/poly-reductions. Agrawal's result also holds for the NE-complete sets under the same hypothesis.

In this paper, we show that if  $\mu_{\rm p}(\rm NP) \neq 0$ , then all NP-complete sets are complete via length increasing, p/poly-reductions. We note that the measure hypothesis on NP is apparently incomparable with Agrawal's hypothesis that one-way permutations exist. Regarding NE-completeness, we show that Agrawal's result can be made unconditional. That is, we unconditionally show that all NE-complete sets are complete via one-to-one, length-increasing, p/poly-reductions.

### 2 Preliminaries

We assume that the readers are familiar with polynomial-time many-one reductions. A language A is polynomial-time Turing reducible to B  $(A \leq_T^p B)$  if there is a polynomial-time oracle Turing M such that  $A = L(M^B)$ . A language A is polynomial-time truth-table reducible to a language B  $(A \leq_{tt}^p B)$  if there exist polynomial-time computable functions g and h such that on input x,  $g(x) = \{q_1, \dots, q_m\}$ , and  $x \in A$  if and only if  $h(x, B(q_1), \dots, B(q_m)) = 1$ . Given a reducibility  $\leq_r^{\alpha}$ , a set S in NP is  $\leq_r^{\alpha}$ -complete for NP if every set in NP is  $\leq_r^{\alpha}$ -reducible to S.

#### 2.1 Resource-Bounded Measure

Lutz [21] introduced resource-bounded measure to study the quantitative structure of complexity classes.

A martingale is a function  $d: \Sigma^* \to \mathbb{Q}$  with the property that for every  $w \in \Sigma^*$ , 2d(w) = d(w0) + d(w1). A martingale d succeeds on a language A if

$$\limsup_{n \to \infty} d(A|n) = \infty,$$

where A|n is the length n prefix of A's characteristic sequence.

Given a time bound t(n), a language L is t(n)-random [6] if no O(t(n))-time computable martingale succeeds on L. A class of languages X has p-measure zero, written  $\mu_p(X) = 0$ , if there exists a polynomial t such that every language in X in not t(n)-random.

Lutz suggested studying the structure of the class NP under the hypothesis "NP does not have p-measure 0," which is written  $\mu_p(NP) \neq 0$ . Since then several believable consequences of this hypothesis have been obtained. For a survey of these results see [22, 24].

#### 2.2 NP-Machine Hypothesis

Our proofs crucially make use of the following hypothesis. Several variants of this hypothesis have been studied earlier [14, 16].

NP-Machine Hypothesis. There exists an NP-machine M and  $\epsilon > 0$  such that M accepts  $0^*$  and no  $2^{n^{\epsilon}}$ -time-bounded Turing machine computes infinitely many accepting computations of M.

it is known the the measure hypothesis implies the NP-machine hypothesis.

**Theorem 1.** (Hitchcock and Pavan [17]) If  $\mu_{\rm p}({\rm NP}) \neq 0$ , then the NP-machine hypothesis holds.

**Observation 1.** Assume that the NP-machine hypothesis is true and let p be any polynomial. Then there exists an NP-machine N that accepts  $0^*$ , and no  $2^{p(n)}$ -time-bounded machine computes infinitely many accepting computations of N.

#### 2.3 Reductions to P-selective Sets

A set S is p-selective if there exists a polynomial-time computable function  $f: \Sigma^* \times \Sigma^* \to \Sigma^*$  such that for all  $x, y, f(x, y) \in \{x, y\}$ , and if at least one of x and y belongs to S, then f(x, y) belongs to S.

Let P-sel denote the class of p-selective sets. For a reduction  $\leq_{\tau}^{\alpha}$  and a class  $\mathcal{C}$ , let

$$R^{\alpha}_{\tau}(\mathcal{C}) = \{ A \mid (\exists B \in \mathcal{C}) A \leq^{\alpha}_{\tau} B \}.$$

**Theorem 2.** (Buhrman and Longpré [10], Wang [28])  $R_{tt}^{p}(P-sel)$  has p-measure 0.

Let  $\leq_{tt}^{t(n)|p}$  denote a truth-table reduction that is computable in t(n) time, but where the number and length of the queries is bounded by a polynomial. It is straightforward to extend the arguments in [10] or [28] to show that Theorem 2 extends to these reductions when t(n) is linear-exponential.

**Theorem 3.** For every  $c \in \mathbb{N}$ , the class  $R_{tt}^{2^{cn}|p}(P-sel)$  has p-measure 0.

### **3** Adaptive versus Nonadaptive Reductions

We now present our solution to Problem 9 of Lutz and Mayordomo [24].

**Theorem 4.** If  $\mu_p(NP) \neq 0$ , then there is a problem that is  $\leq_T^p$ -complete for NP but not  $\leq_{tt}^p$ -complete.

*Proof.* Assume that  $\mu_p(NP) \neq 0$ . From Theorem 1 and Observation 1 we obtain an NP-machine M that accepts  $0^*$  such that no  $2^{n^2}$ -time machine can compute infinitely many of its accepting computations.

For each n, let  $a_n$  be the lexicographically maximum accepting computation of  $M(0^n)$ . Let a be the infinite sequence  $a = a_0 a_1 a_2 \dots$  Let

 $A = \{ \langle x, w \rangle \mid x \in \text{SAT and } w \text{ is an accepting computation of } M(0^{|x|}) \},\$ 

$$B = L(a) = \{ x \mid x < a \},\$$

where < is the standard dictionary order. Observe that B is a p-selective set. Let

$$C = 0A \cup 1B.$$

Then C is  $\leq_{\mathrm{T}}^{\mathrm{p}}$ -complete for NP: to decide whether  $x \in \mathrm{SAT}$ , we can adaptively query B to find  $a_{|x|}$  and then ask if  $\langle x, a_{|x|} \rangle \in A$ .

Suppose that C is  $\leq_{tt}^{p}$ -complete for NP. Then for every  $L \in NP$ ,  $L \leq_{tt}^{p} C$  via some reduction (g, h).

**Claim 1.** For all but finitely many x, all queries of g(x) to strings of the form  $0\langle y, w \rangle$  must satisfy  $|y| \leq |x|$ .

Proof of Claim 1. Consider the following algorithm.

input  $0^n$ ; for all  $x \in \{0, 1\}^{< n}$ : compute g(x); for all queries in g(x) that are of the form  $0\langle y, w \rangle$ , where |y| = n: if w is an accepting computation of  $M(0^n)$ output w and halt;

This algorithm runs in  $O(2^n \cdot \text{poly}(n))$  time, and would compute infinitely many accepting computations of M if the claim is false.  $\Box$  Claim 1

Claim 2.  $L \leq_{tt}^{2^n \mid p} B.$ 

Proof of Claim 2. Given x, compute g(x). By Claim 1, all queries of g(x) to strings of the form  $0\langle y, w \rangle$  must satisfy  $|y| \leq |x|$ . We can decide whether these queries are in A in  $2^n$  time by checking if  $y \in SAT$  in exponential time and whether w is an accepting computation of  $M(0^{|y|})$  in polynomial time. Our reduction to B simply solves the queries to A directly.  $\Box$  Claim 2

Since B is a left-cut, it is p-selective, so it follows from Claim 2 that NP  $\subseteq R_{tt}^{2^n \mid p}$ (P-sel). By Theorem 3, this implies  $\mu_p(NP) = 0$ , a contradiction.

### 4 Nondeterministic versus Deterministic Reductions

**Definition 1.** [1, 20] A language A is strong nondeterministic many-one reducible to a language B, written  $A \leq_{\mathrm{m}}^{\mathrm{SNP}} B$ , if there is a nondeterministic polynomial-time machine M such that the following conditions hold.

- On an input x, every path of M either outputs a string y or outputs the special symbol "?". At least one path outputs a string.
- If x belongs to A, then every output y belongs to B, and if x does not belong to A, then every output y does not belong to B.

Adleman and Manders [1] also called this  $\gamma$ -reducibility and denoted it  $\leq_{\gamma}$ .

Long [20] showed that the following are equivalent:

- for all  $A, B, A \leq_{\mathrm{m}}^{\mathrm{SNP}} B$  implies  $A \leq_{\mathrm{T}}^{\mathrm{p}} B$
- every NPMV total function has a polynomial-time refinement.

The latter has been called Proposition Q in [14]. To separate  $\leq_{m}^{SNP}$ -completeness from  $\leq_{T}^{p}$ -completeness for NP, we clearly need a hypothesis that at least implies Q is false. The NP-machine hypothesis fits the bill:

**Theorem 5.** If the NP-machine hypothesis holds, then there is a problem that is  $\leq_{m}^{SNP}$ -complete for NP but not  $\leq_{T}^{p}$ -complete.

*Proof.* By Observation 1, there exists an NP machine M that accepts  $0^*$  for which no  $2^{3n}$ -time bounded machine can compute infinitely many accepting computations. Consider the following language L

 $L = \{ \langle x, a \rangle \mid x \in \text{SAT and } a \text{ is an accepting computation of } M(0^{|x|}) \}.$ 

Then  $L \in NP$ , and we claim that L is strong nondeterministic many-one complete. Consider a nondeterministic machine N that on input x guesses a string a, and if a is an accepting computation of  $M(0^{|x|})$ , then it outputs  $\langle x, a \rangle$ . If a is not an accepting computation of  $M(0^{|x|})$ , then N outputs?. Then N is a strong nondeterministic many-one reduction from SAT to L. It follows that L is strong nondeterministic many-one complete for NP.

We will show that L is not Turing complete for NP. Suppose to the contrary that it is Turing complete. Consider the following language S.

 $S = \{ \langle 0^n, w \rangle \mid w \text{ is a prefix of an accepting computation of } M(0^n) \}.$ 

Since S in in NP, there is a polynomial-time oracle Turing machine R such that  $S = R^L$ . Consider the following procedure  $\mathcal{A}$  that tries to compute accepting computations of M.

- 1. Input  $0^n$ .
- 2. Set  $y = \epsilon$ .
- 3. Run  $R(\langle 0^n, y0 \rangle)$ . When R generates a query  $q = \langle x, z \rangle$ , |x| = t do the following:
  - (a) If z is not an accepting computation of  $M(0^t)$ , then continue simulation of R with answer "No".
  - (b) Else, z is an accepting computation of  $M(0^t)$ .
  - (c) If  $t \ge n$ , then Output "Unsuccessful", print z and halt.
  - (d) Otherwise, decide whether  $\langle x, z \rangle \in L$  by checking whether  $x \in SAT$ . Since t < n this takes at most  $2^n$  time. Use this answer to continue the simulation.
- 4. If R accepts  $\langle 0^n, y0 \rangle$ , then set y = y0. Else set y = y1.
- 5. If y is an accepting computation of  $M(0^n)$ , then output y and halt. Else, GoTo Step 3.

Observe that the most expensive step in the above computation is Step 3d. This takes  $2^n$  time. Since this step is repeated at most polynomial number of steps, the above algorithm halts in  $2^{2n}$  steps.

Next we make two claims about the behavior of the algorithm  $\mathcal{A}$ .

**Claim 3.** If  $\mathcal{A}(0^n)$  outputs "Unsuccessful" for infinitely many n, then there is a  $2^{3n}$ -time algorithm that outputs infinitely many accepting computations of  $M(0^n)$ .

Proof of Claim 3. Observe that if  $\mathcal{A}(0^n)$  outputs "Unsuccessful", then there exists a  $t \geq n$  and  $\mathcal{A}(0^n)$  outputs an accepting computation of  $M(0^t)$ . Thus if there exist infinitely many n for which  $\mathcal{A}(0^n)$  outputs "Unsuccessful", then there exists infinitely many t for which there exists  $n \leq t$ , and  $\mathcal{A}(0^n)$  outputs an accepting computation of  $M(0^t)$ . Now consider the following algorithm: On input  $0^t$ , run  $\mathcal{A}(0^j)$ ,  $1 \leq j \leq t$ . If any of the runs of  $\mathcal{A}$  outputs an accepting computation of  $M(0^t)$ , then output that accepting computation.

This algorithm outputs an accepting computation of  $\mathcal{A}(0^t)$  for infinitely many t. The running time of the algorithm is bounded by  $\sum_{j=1}^{t} 2^{2j} \leq 2^{3t}$ . This establishes the claim.  $\Box$  Claim 3

Claim 4. If  $\mathcal{A}(0^n)$  does not output "Unsuccessful", then it outputs an accepting computation of  $M(0^n)$  in time  $2^{2n}$ .

Proof of Claim 4. Observe that  $\mathcal{A}(0^n)$  is trying to compute an accepting computation of  $M(0^n)$  by doing a prefix search. This is accomplished by running the Turing reduction R, and whenever the reduction generates a query it is attempting to find the answer to the query without actually making the query. Thus if all the queries are answered correctly, it will compute an accepting computation of  $M(0^n)$ . We argue that  $\mathcal{A}(0^n)$  computes all query answers correctly. Let  $q = \langle x, y \rangle$  be a query that is generated.

If y is not an accepting computation of M, then q does not belong to L. Thus  $\mathcal{A}$  answers the query correctly in 3a. So assume y is an accepting computation of  $M(0^t)$ . Since  $\mathcal{A}(0^n)$  does not output "Unsuccessful", t < n. Thus the algorithm reaches Step 3d. In this step, it decides whether  $x \in SAT$  by a running a deterministic algorithm for SAT. Thus the query answer is computed correctly in this step.

Thus  $\mathcal{A}(0^n)$  computes all query answers correctly. Thus  $\mathcal{A}(0^n)$  outputs an accepting computation of  $M(0^n)$ . Recall that the running time of  $\mathcal{A}$  is bounded by  $2^{2n}$ .  $\Box$  Claim 4

Now, if  $\mathcal{A}(0^n)$  outputs "Unsuccessful" for infinitely many n, then, by Claim 3, there is a  $2^{3n}$ -time algorithm that computes infinitely many accepting computations of  $M(0^n)$ . This contradicts the NP-machine hypothesis. Thus for all but finitely many n,  $\mathcal{A}(0^n)$  does not output "Unsuccessful". Thus, by Claim 4, for all but finitely many n,  $\mathcal{A}(0^n)$  outputs an accepting computation of  $M(0^n)$  in time  $2^{2n}$ . This again contradicts the NP-machine hypothesis.

Thus there is no Turing reduction from S to L. Thus L is not Turing complete for NP.  $\Box$ 

By Theorem 1, we immediately have the following.

**Corollary 1.** If  $\mu_p(NP) \neq 0$ , there is a problem that is  $\leq_m^{SNP}$ -complete for NP but not  $\leq_T^p$ -complete.

### 5 Length-Increasing Reductions and Polynomial-Size Circuits

In this section we study one-to-one, length-increasing reductions. (All reductions in this section are many-one reductions. We say that a many-one reduction f is length-increasing if |f(x)| > |x| for all strings x and that f is one-to-one if for all strings  $x \neq y$ ,  $f(x) \neq f(y)$ .)

Berman's proved [7] that every  $\leq_{m}^{p}$ -complete set for E is also is complete under one-to-one, length-increasing reductions. This proof makes essential use of the fact that E is closed under complementation, so it does not go through for nondeterministic classes. As a partial result, Ganesan and Homer [15] showed that every  $\leq_{m}^{p}$ -complete set for NE is complete under one-to-one, exponentially-honest reductions. See also the survey paper [19] by Homer.

Agrawal [3] showed that if one-way permutations exist, then many-one complete sets for NP and NE are complete via one-to-one, length-increasing, p/poly reductions. (A p/poly reduction is computed by a nonuniform family of polynomial-size circuits, one for each input length.) A well-known fact is that coNE  $\subseteq$  NE/poly: to determine if a string x is not in an NE language, we can give as advice the number of strings in the language at x's length. Then an NE machine can guess all of these strings and determine whether or not x is in the language. We make use of this idea and Berman's technique to prove the following theorem.

**Theorem 6.** Every set that is  $\leq_{m}^{p}$ -complete for NE is complete under one-to-one, length-increasing, p/poly reductions.

*Proof.* Let A be any  $\leq_{\mathrm{m}}^{\mathrm{p}}$ -complete set for NE and let K be the standard complete set. It suffices to show that K reduces to A via a one-to-one, length-increasing, p/poly reduction. Let  $\{f_i\}$  be an enumeration of all polynomial-time reductions. Let N be an NE machine for K. Consider the following machine M.

Machine M(i, x, a)let n = |x|;let  $(q_0, r_0, \ldots, q_n, r_n) = a$ ; (reject if a is not of this form) if  $|f_i(i, x, a)| \leq |x|$ guess a set X of  $q_n$  strings of length  $\leq n$ and witnesses for membership in A; if valid witnesses are found for all strings in X: accept if  $f_i(i, x, a) \notin X$ ; reject if  $f_i(i, x, a) \in X$ ; else reject; for each l, let  $a_l = (q_0, r_0, \dots, q_l, r_l);$ if  $\exists y < x$  such that  $f_i(i, x, a) = f_i(i, y, a_{|y|})$ guess a set Y of  $r_n$  strings of length  $\leq n$ and witnesses for membership in K; if valid witnesses are found for all strings in Y: accept if  $y \notin Y$ ; reject if  $y \in Y$ ; else reject;

simulate N(x) and output its decision;

Observe that M is an NE machine.

**Claim 5.** Let  $f_j$  be any reduction from M to A. Define the sequence of advice strings

$$a_n = (|A_{\leq 0}|, |K_{\leq 0}|, \dots, |A_{\leq n}|, |K_{\leq n}|).$$

Then  $f_j$  is one-to-one and polynomially-honest on inputs of the form  $(j, x, a_{|x|})$ . Also,  $g(x) = (j, x, a_{|x|})$  reduces K to M.

Proof of Claim 5. Suppose that for some x,  $|f_j(j, x, a_{|x|})| \leq |x|$ . Observe that whenever M finds valid witnesses for all strings in X, it has  $X = A_{<|x|}$ .

- Suppose that  $f_j(j, x, a_{|x|}) \notin A$ . Then on some path M will have  $X = A_{\leq |x|}$ , and accept  $(j, x, a_{|x|})$ .
- Suppose that  $f_j(j, x, a_{|x|}) \in A$ . Then M will always reject.

In either case, we have  $(j, x, a_{|x|}) \in M$  iff  $f_j(j, x, a_{|x|}) \notin A$ , a contradiction. Therefore for all x,  $|f_j(j, x, a_{|x|})| > |x|$ , so  $f_j$  is polynomially-honest on inputs of this form.

Suppose f is not one-to-one on inputs of the specified form. Let x be minimal such that there exists y < x such that  $f_j(j, x, a_{|x|}) = f_j(j, y, a_{|y|})$ . Observe that  $(j, y, a_{|y|}) \in M$  iff  $y \in K$  because  $M(j, y, a_{|y|})$  simulates N(y). Whenever M finds valid witnesses for all strings in Y, it has  $Y = K_{\leq |x|}$ .

- Suppose that  $y \notin K$ . On some path M will have  $Y = K_{\leq |x|}$  and accept  $(j, x, a_{|x|})$ .
- Suppose that  $y \in K$ . Then on every path M rejects  $(j, x, a_{|x|})$ .

Therefore we have  $(j, x, a_{|x|}) \in M$  iff  $y \notin K$  iff  $(j, y, a_{|y|}) \notin M$ . Because  $f_j(j, x, a_{|x|}) = f_j(j, y, a_{|y|})$ , this means that  $f_j$  is not a reduction of M, a contradiction.

Finally, it follows that  $x \in K$  if and only if  $(j, x, a_{|x|}) \in M$  because  $M(j, x, a_{|x|})$  always ends up simulating N(x).

Define  $f(x) = f_j(j, x, a_{|x|})$ . This is one-to-one, polynomially-honest, and reduces K to A. Since K is the standard complete set that is paddable, there exists an one-to-one, length-increasing, p/poly-reduction from K to A.

Next we will show that if NP does not have p-measure zero, then all NP-complete sets are complete via length-increasing p/poly reductions. In the proof we will consider whether a language R has the following property.

**Property 1.** There is a  $2^{p(n)}$ -time computable function f such that for every n,  $f(0^n)$  either outputs  $\perp$  or outputs a tuple  $\langle a, b, u, v \rangle$ . Whenever  $f(0^n) = \langle a, b, u, v \rangle$ , the following hold.

- |a| = |b| = n.
- $R(a)R(b) \neq uv$ , and uv is either 00 or 11.

And for infinitely many  $n, f(0^n) \neq \bot$ .

Informally, f either finds two strings such that at least one of them is in R, or finds two strings such that at least one of them does not belong to R.

**Lemma 1.** If R has Property 1, then R is not p(n)-random.

Proof. We describe a martingale d that can win an infinite amount of money while betting on R. Let d(n) denote the amount of money that the martingale has before it starts betting on strings of length n. Before starting betting on strings of length n, the martingale runs  $f(0^n)$ . If  $f(0^n) = \bot$ , then d does not bet on any string of length n. Suppose  $f(0^n) = \langle a, b, u, v \rangle$ . Without loss of generality we can assume a < b. Consider the case uv = 00. In this case at least one of a and b must be in R. The martingale bets 1/3rd of its amount on  $a \in R$ . If a really belongs to R, then d does not bet on any other string of length n. So if  $a \in R$ , then d(n+1) = 4d(n)/3. However, if  $a \notin R$ , then d is left with capital 2d(n)/3. However, since at least one of a and b must belong to R. Now d bets all its money on  $b \in R$ . Thus in this case also d(n+1) = 4d(n)/3. The case uv = 11 is handled via a symmetric argument.

Since  $f(0^n) \neq \bot$  for infinitely many n, for infinitely many n,  $d(n+1) \ge 4d(n)/3$ . Thus d(n) approaches infinity as n tends to  $\infty$ . Since f runs in  $2^{p(n)}$ -time, d runs in time O(p(n)). Thus R is not p(n)-random.

Now we are ready to prove the theorem regarding complete sets for NP.

**Theorem 7.** If  $\mu_p(NP) \neq 0$ , then every NP-complete language is complete under length-increasing, p/poly reductions.

*Proof.* Let L be any NP-complete language. We show that there is a p/poly, length-increasing reduction from SAT to L. We first define an intermediate language S such that SAT is p/poly, length increasing reducible to S, and S is honest polynomial-time reducible to L. Combing these two reductions we obtain the desired reduction from SAT to L. Let  $L \in \text{DTIME}(2^{n^k})$ .

If NP does not have p-measure 0, then there is an  $n^2$ -random language R in NP. The randomness of R implies that both R and  $\overline{R}$  have at least one string at each length. Let

$$S = \{ \langle x, y, z \rangle \mid |x| = |y| = |z| \text{ and } MAJ\{x \in R, y \in SAT, z \in R\} = 1 \}.$$

It is clear that S is NP. For every n, fix two strings  $a_n$  and  $b_n$  of length n such that  $a_n \in R$ and  $b_n \notin R$ . Consider the following reduction from SAT to S: Given an input y of length n the reduction outputs  $\langle a_n, y, b_n \rangle$ . Now  $y \in SAT \Leftrightarrow \langle a_n, y, b_n \rangle \in S$ . The reduction takes  $a_n$  and  $b_n$  as advice. It is clear that this reduction is length increasing. Therefore we have established that SAT is p/poly, length-increasing reducible to S.

Since S is in NP and L is NP-complete, there is a many-one reduction f from S to L. We now argue that f must be a honest reduction on strings of form  $\langle x, y, z \rangle$  where |x| = |y| = |z|.

Claim 6. Let

$$T=\{\langle x,y,z
angle \ | \ |x|=|y|=|z|\}.$$

For all but finitely many strings w from T,  $|f(w)| \ge n^{1/k}$ .

Proof of Claim 6. Consider the following set

$$U = \{ w = \langle x, y, z \rangle \in T \mid |x| = n, |f(w)| < n^{1/k} \}.$$

We show that if U is infinite, then R has Property 1.

Recall that L can be decided in time  $2^{n^k}$ . Thus if a string w belongs to U, then the membership of f(w) in L can be decided in time  $2^{|f(w)|^k} < 2^n$ . Since f is a many-one reduction from S to L, for every string w in U, its membership in S can be computed in time  $2^n$ .

Define a function f as follows. In input  $0^n$ , cycle through all tuples  $w = \langle x, y, z \rangle$ , |x| = |y| = |z| = n, and check if  $w \in U$  by computing f(w). If none of the w's are in U, then output  $\bot$ . Else, let  $w = \langle x, y, z \rangle$  be the first string that belongs to U.

Compute the membership of w in S. We first consider the case  $w \in S$ . In this case,

$$MAJ\{x \in R, y \in SAT, z \in R\} = 1.$$

Thus it can not be the case that both x and z are out of R. So f outputs  $\langle x, z, 0, 0 \rangle$ . Similarly, if  $w \notin S$ , then it cannot be the case that both x and z are in S. So f outputs  $\langle x, z, 1, 1, \rangle$ .

Observe that the running time of f is bounded by  $O(2^{3n})$ . If U is infinite, then for infinitely many  $n, f(0^n) \neq \bot$ . So, if U is infinite, then R has Property 1, and by Lemma 1, R is not 3n-random. Since R is  $n^2$ -random U is finite.

Thus for all but finitely many strings from T,  $|f(w)| \ge n^{1/k}$ .  $\Box$  Claim 6

Now consider the following reduction g from SAT to L: On input y of length n, output  $f(\langle a_n, y, b_n \rangle)$ . By Claim 6,  $|f(\langle a_n, y, b_n \rangle)| \ge n^{1/k}$ . Thus g is an honest, p/poly-reduction from SAT to L. Since SAT is paddable, there exists a length-increasing p/poly-reduction from SAT to L. Thus L is complete via length-increasing, p/poly reductions.

## 6 Conclusion

We now know that the measure hypothesis separates nearly all polynomial-time completeness notions for NP. It would be interesting to separate completeness notions for NP under weaker hypotheses such as "NP is hard on average".

Theorem 5 gives evidence that when we give more resources to the reductions, we obtain a richer class of complete sets. What happens when we decrease the resource bound of the reductions? Agrawal et al [4, 2] showed that  $NC^0$ -completeness and  $AC^0$ -completeness for NP coincide whereas  $AC^0$ -completeness and  $AC^0$ [mod2]-completeness for NP differ. It would be interesting to extend these results other resource bounds.

Results of Agrawal [3] and results in Section 5 indicate that complete sets for NP and NE are complete under one-to-one, length-increasing reductions. However these reductions need polynomial advice. Can we eliminate the advice?
