

NP-Hard Sets are Exponentially Dense Unless $\text{coNP} \subseteq \text{NP/poly}$

Harry Buhrman* John M. Hitchcock†

Abstract

We show that hard sets S for NP must have exponential density, i.e. $|S_{=n}| \geq 2^{n^\epsilon}$ for some $\epsilon > 0$ and infinitely many n , unless $\text{coNP} \subseteq \text{NP/poly}$ and the polynomial-time hierarchy collapses. This result holds for Turing reductions that make $n^{1-\epsilon}$ queries.

In addition we study the instance complexity of NP-hard problems and show that hard sets also have an exponential amount of instances that have instance complexity n^δ for some $\delta > 0$. This result also holds for Turing reductions that make $n^{1-\epsilon}$ queries.

1 Introduction

The density of NP-complete and hard sets was an early object of study in complexity theory. Assuming that P is not equal to NP, the real question is how many instances are indeed hard? In principle it could be that $\text{P} \neq \text{NP}$ only because of a few instances that are hard to compute, but almost all instances can be decided by an efficient algorithm. This question was formalized and investigated in a large body of work starting with that of Berman and Hartmanis [2], Meyer and Paterson [9], Fortune [4], Karp and Lipton [7], Mahaney [8], and many others.

It is problematic for this question to just focus on a fixed NP-complete set for the following reason. Suppose that $\text{P} \neq \text{NP}$, and suppose there is

a machine M that runs in polynomial time on all but 2^{n^ϵ} many formulae of length n . We can then solve SAT in randomized polynomial time, by simple padding. Given any formula ϕ we can construct 2^n many different other formulae ϕ'_i of roughly the same length that are satisfiable if and only if ϕ is satisfiable. It is easy to see that M will with high probability run in polynomial time on a randomly chosen ϕ_i . For this reason the focus has been on the density of all NP-complete or NP-hard problems. This simple padding trick cannot work for an arbitrary NP-complete problem, since the reduction can map the equivalent formula ϕ_i back to the original ϕ . Therefore attention has been on the density of NP-complete and NP-hard sets under various types of reductions.

Mahaney [8] showed that if there exists a *sparse* many-one hard set for NP then $P = NP$. A set is sparse if for every length n it contains no more than $p(n)$ strings for some polynomial p . This result shows that many-one hard sets for NP are super-polynomially dense unless $P = NP$. Mahaney's result has been extended to weaker notions of reductions, notably by Ogihara and Watanabe for bounded truth-table reductions [10]. But it remains an open question to show the same result for $\log(n)$ -truth-table reductions, let alone for the more general Turing reductions. Karp and Lipton [7] showed that if there exists a sparse Turing hard set for NP, or equivalently if NP is in P/poly, then the polynomial-time hierarchy collapses to its second level ($\Sigma_2^P = \Pi_2^P$). Hence Turing hard sets for NP are also super-polynomially dense unless the polynomial-time hierarchy collapses.

In this paper we improve these results from sparse to *subexponential* density. A set S has subexponential density if for every $\epsilon > 0$, $\|S_{=n}\| \leq 2^{n^\epsilon}$ for almost all n . We show that if there exists an NP-hard set with *subexponential* density then $\text{coNP} \subseteq \text{NP/poly}$ and by a result of Yap [12] it follows that the polynomial-time hierarchy collapses to its third level ($\Sigma_3^P = \Pi_3^P$). Our result holds for Turing reductions that make $n^{1-\epsilon}$ queries (any $\epsilon > 0$). This shows that NP-hard sets have exponential density 2^{n^ϵ} for some $\epsilon > 0$, unless $\text{coNP} \subseteq \text{NP/poly}$. This is the best possible result for NP-hard sets with respect to their density, since simple padding shows that for every $\epsilon > 0$ there exists an NP-hard set with density less than 2^{n^ϵ} . Our results make use of a recent combinatorial lemma due to Fortnow and Santhanam [3].

Another way to make the notion of hard instances precise is that of *instance complexity* due to Orponen et. al. [11]. The instance complexity of an instance x with respect to some set A , $\text{ic}(x : A)$, is the size of the smallest (polynomial-time) program p that correctly decides x and for all other

instances either outputs no decision or the correct decision. It is easy to see that $\text{ic}(x : A) \leq |x| + O(1)$. Strings with high instance complexity do not have small efficient programs that decide them. The instance complexity of NP-complete sets has been studied. The best known bound [11] is that if every instance of SAT (or any NP-complete problem) has logarithmic instance complexity, i.e. $\text{ic}(\phi : \text{SAT}) \leq O(\log |\phi|)$ for all ϕ , then $\text{P} = \text{NP}$. We show that if SAT has sublinear instance complexity, that is $\text{ic}(\phi : \text{SAT}) \leq |\phi|^{1-\epsilon}$ for all ϕ and some $\epsilon > 0$, then $\text{coNP} \subseteq \text{NP/poly}$.

2 Preliminaries

We shall consider decision problems for languages over the alphabet $\Sigma = \{0, 1\}$. The length of a string $x \in \{0, 1\}^*$ is denoted $|x|$; λ denotes the empty string. Given strings x, y , we denote with $x \cdot y$ the concatenation of x and y : xy . We represent the pair $\langle x, y \rangle$ as the string $\bar{x}10y$, where \bar{x} denotes x with each of its characters doubled.

For a set B and number n , $B_{=n} = \{x \in B \mid |x| = n\}$ and $B_{\leq n} = \{x \in B \mid |x| \leq n\}$. The cardinality of a finite set C is denoted $\|C\|$.

A set S has subexponential density if for every $\epsilon > 0$, $\|S_{=n}\| \leq 2^{n^\epsilon}$ for all but finitely many n . We write SUBEXPD for the class of languages with subexponential density. A set is exponentially dense if it does not have subexponential density.

An AND-function for a set A is a polynomial-time computable function g such that for all strings x_1, x_2, \dots, x_n , $g(x_1, x_2, \dots, x_n) \in A$ iff $x_i \in A$ for all i . Similarly, an OR-function g satisfies $g(x_1, x_2, \dots, x_n) \in A$ iff $x_i \in A$ for some i . We say that g has order s if $|g(x_1, \dots, x_n)| = O((\sum_{i=1}^n |x_i|)^s)$. Observe that if g is an AND-function for A , then g is also an OR-function for \bar{A} .

3 Reductions

To introduce the technique we will begin with the easier case of many-one reductions. This result has the corollary that if $\overline{\text{SAT}}$ many-one reduces to a set of subexponential density, then $\text{coNP} \subseteq \text{NP/poly}$.

Theorem 3.1. *Let A be any set that has an AND-function. If there is a set S with subexponential density such that $A \leq_m^p S$ then $A \in \text{NP/poly}$.*

Proof. Let $g(x_1, \dots, x_n)$ be the AND-function for A . Let f be the many-one reduction from A to S . We say that a string $z \in S$ is NP-proof for $x \in A$, with $|x| = n$, iff there exist x_1, \dots, x_n , such that for all i , $|x_i| = n$ and there exists an i , with $x = x_i$, and in addition $f(g(x_1, \dots, x_n)) = z$.

The idea is to show that there exists a string $z_1 \in S$ that is NP-proof for half the strings in $A_{=n}$. We will then recurse on the remaining strings in $A_{=n}$, for which z_1 is not NP-proof, until we end up with a sequence of at most n strings z_1, \dots, z_k such that for all $x \in A_{=n}$ there is an i such that z_i is NP-proof for x . These NP proofs serve as advice to show that $A \in \text{NP/poly}$.

First observe that if z is NP-proof for precisely t strings $x \in A$ then

$$\|\{ \langle x_1, \dots, x_n \rangle \mid |x_i| = n \text{ and } f(g(x_1, \dots, x_n)) = z \}\| \leq t^n \quad (3.1)$$

Assume that f and g both run in time n^c for some c . Let $m_n = n^{2c^2}$, hence $|f(g(x_1, \dots, x_n))| \leq m_n$. Since S has subexponential density, for large enough n it holds that $\|S_{\leq m_n}\| < 2^n$.

Let t be the largest such that some z_1 is NP-proof for t elements of length n in A . Since for every n -tuple $\langle x_1, \dots, x_n \rangle$ with for all i , $x_i \in A$, $f(g(\langle x_1, \dots, x_n \rangle))$ maps to some string z in $S_{\leq m_n}$, we now have:

$$t^n \|S_{\leq m_n}\| \geq \|A_{=n}\|^n \quad (3.2)$$

and hence

$$t^n 2^n \geq \|A_{=n}\|^n \quad (3.3)$$

which implies that $t \geq \|A_{=n}\|/2$, and hence z_1 is NP-proof for half the elements in A of length n . The proof now continues by finding a z_2 that is NP-proof for half of the elements in A for which z_1 is not NP-proof, resulting ultimately in the desired sequence z_1, \dots, z_k ($k \leq n$). The inductive generation of z_i is possible because all the strings in A for which none of the z_1, \dots, z_{i-1} is NP-proof, let's call them A' , have the following property. For every $y_1, \dots, y_n \in A'$ it holds that $f(g(y_1, \dots, y_n)) \in S \setminus \{z_1, \dots, z_{i-1}\}$. Hence the counting arguments in equations (3.1), (3.2), and (3.3) still hold for A' . \square

Our main technical tool, Lemma 3.2 below, is a generalization of Theorem 3.1. Instead of a many-one reduction to a subexponentially dense set, we consider a nondeterministic disjunctive reduction to a family of sets where the density can be exponential.

Definition. Let $\mathcal{B} = (B_n \mid n \geq 0)$ be a family of subsets of $\{0, 1\}^*$. We say that A NP-reduces to \mathcal{B} if there is an NPMV function N such that for all n , for all $x \in \{0, 1\}^n$, $x \in A$ iff at least one output of $N(x)$ is in B_n .

Lemma 3.2. *Let A have an AND-function of order s and let $\alpha < 1/s$. Let $\mathcal{B} = (B_n \mid n \geq 0)$ be a family of sets with $\|B_n\| \leq 2^{n^\alpha}$ for sufficiently large n . If A NP-reduces to \mathcal{B} , then $A \in \text{NP/poly}$.*

Proof. Let M compute the NPMV function for the reduction from A to \mathcal{B} . Let g be the AND-function for A . For simplicity we assume that for all $x_1, \dots, x_n \in \{0, 1\}^m$, the length of $g(x_1, \dots, x_n)$ is exactly $(nm)^s$. The general case when the length is $O((nm)^s)$ is similar.

Choose a constant k so that $\frac{k}{k+1} \geq \alpha s$. Fix an input length m , let $n = m^k$, and let $N = (nm)^s$. Note that we have

$$\|B_N\| \leq 2^{N^\alpha} = 2^{m^{(k+1)s\alpha}} \leq 2^{m^k} = 2^n.$$

For any $x \in \{0, 1\}^m$,

$x \in A \iff$ there exist $x_1, \dots, x_n \in \{0, 1\}^m$ with $x_i = x$ for some i such that M on input $g(x_1, \dots, x_n)$ outputs some string $z \in B_N$.

Call such a string z an NP-proof that $x \in A$. As in the proof of Theorem 3.1, we claim that there exists a collection of at most m strings z_1, \dots, z_l such that each $x \in A_{=m}$ has an NP-proof in the collection.

Suppose that z is an NP-proof for exactly t strings in $A_{=m}$. Then

$$\|\{ \langle x_1, \dots, x_n \rangle \mid M(g(x_1, \dots, x_n)) \text{ outputs } z \}\| \leq t^n.$$

Let t be the maximal such that some string z is an NP-proof for t strings. Then

$$\|A_{=m}\|^n \leq \|B_N\| \cdot t^n \leq 2^n t^n,$$

so $t \geq \|A_{=m}\|/2$. Therefore there is a string z_1 that works for at least half of the strings in $A_{=m}$. Repeating this argument yields a string z_2 that works for at least half of the remaining strings. After at most m repetitions we have NP-proofs for all the strings. \square

As our first application of Lemma 3.2 we extend Theorem 3.1 to disjunctive reductions.

Theorem 3.3. *If A has an AND-function and $A \leq_d^p$ SUBEXPD, then $A \in \text{NP/poly}$.*

Proof. Suppose that $A \leq_d^p S \in \text{SUBEXPD}$ via a reduction g in $p(n)$ time. Define an NPMV function N that on input x guesses and outputs one of the queries in $g(x)$. Let $B_n = S_{\leq p(n)}$. Then A NP-reduces to the family $(B_n \mid n \geq 0)$ via N .

Let $\alpha < 1/s$ where s is the order of the AND-function. We have $\|B_n\| \leq 2^{n^\alpha}$ for sufficiently large n because S has subexponential density. By Lemma 3.2 we have $A \in \text{NP/poly}$. \square

We apply Theorem 3.3 with $\overline{\text{SAT}}$ to obtain the following:

Theorem 3.4. *If $\text{coNP} \not\subseteq \text{NP/poly}$, then every \leq_d^p -hard set for coNP is exponentially dense.*

Allender, Hemachandra, Ogiwara, and Watanabe [1] showed that if $A \leq_{\text{btt}}^p$ -reduces to a sparse set, then $A \leq_d^p$ -reduces to another sparse set. Part of the proof shows that the complement of any sparse set disjunctively reduces to a sparse set. This argument also applies to subexponentially dense sets. For completeness we include a proof. Here we write that S has density $d(n)$ if $\|S_{\leq n}\| = d(n)$.

Lemma 3.5. *Let S be a set with density $d(n)$. Then there is a set T with density at most $nd(n) + n$ such that $\overline{S} \leq_d^p T$. In particular, if $S \in \text{SUBEXPD}$, then $\overline{S} \leq_d^p T$ for some $T \in \text{SUBEXPD}$.*

Proof. We isolate the part we need of the proof in [1]. Let T be the set of all $0^n 1 w b$ where b is a bit and w has an extension in $S_{=n}$, but $w b$ does not have an extension in $S_{=n}$. If $S_{=n} = \emptyset$, we add $0^n 1$ to T .

We claim that a string y is in $\overline{S}_{=n}$ if and only if y has a prefix z such that $0^n 1 z \in T$.

- If $y \notin S$ and $S_{=n} \neq \emptyset$, then let z be the longest prefix of y that has an extension in S . The string $0^n 1 z$ is in T . If $S_{=n} = \emptyset$, then $0^n 1$ is in T , so the claim holds for $z = \lambda$.
- If $y \in S$, then every prefix z of y has an extension in S and $0^n 1 z \notin T$.

Therefore $\overline{S} \leq_d^p T$ via the reduction that lists the prefixes of its input.

For each length n , we added at most $(n + 1)\|S_{=n}\| + 1$ strings to T . Therefore $\|T_{\leq n}\| \leq \sum_{m=0}^{n-1} (m + 1)\|S_{=m}\| + 1 \leq nd(n) + n$. \square

Theorem 3.3 and Lemma 3.5 yield the following for conjunctive reductions.

Theorem 3.6. *If A has an OR-function and $A \leq_c^p$ SUBEXPD, then $A \in \text{coNP/poly}$.*

Proof. Suppose that $A \leq_c^p S \in \text{SUBEXPD}$. Then $\overline{A} \leq_d^p \overline{S}$ and by Lemma 3.5 there is a $T \in \text{SUBEXPD}$ such that $\overline{S} \leq_d^p T$. Composing reductions yields $\overline{A} \leq_d^p T$, so $\overline{A} \in \text{NP/poly}$ by Theorem 3.3, because the OR-function for A is an AND-function for \overline{A} . \square

Theorem 3.7. *If $\text{coNP} \not\subseteq \text{NP/poly}$, then every \leq_c^p -hard set for NP is exponentially dense.*

Our next theorem concerns query-bounded Turing reductions. In the proof we use techniques from [1, 5] to convert the Turing reduction into an NP disjunctive reduction.

Theorem 3.8. *Let A have an AND-function of order s and let $\alpha < 1/s$. If $A \leq_{n^\alpha\text{-T}}^p \text{SUBEXPD}$, then $A \in \text{NP/poly}$.*

Proof. Suppose $A \leq_{n^\alpha\text{-T}}^p S \in \text{SUBEXPD}$ via M . Fix an input length n . For an input $x \in \{0, 1\}^n$, consider using each $z \in \{0, 1\}^{n^\alpha}$ as the sequence of yes/no answers to M 's queries. Each z causes M to produce a sequence of queries $w_1^{x,z}, \dots, w_{n^\alpha}^{x,z}$ and an accepting or rejecting decision. (We can assume that M always makes n^α queries.) Let $Z_x \subseteq \{0, 1\}^{n^\alpha}$ be the set of all query answer sequences that cause M to accept x . Then we have $x \in A$ if and only if

$$(\exists z \in Z_x)(\forall 1 \leq j \leq n^\alpha) S[w_j^{x,z}] = z[j],$$

which is equivalent to

$$(\exists z \in Z_x)(\forall 1 \leq j \leq n^\alpha) z[j] \cdot w_j^{x,z} \in \overline{S} \oplus S,$$

where $\overline{S} \oplus S$ is the disjoint union $\{0x \mid x \in \overline{S}\} \cup \{1x \mid x \in S\}$.

By Lemma 3.5 there is a set $T \in \text{SUBEXPD}$ such that $\overline{S} \leq_d^p T$. Let $U = T \oplus S$. We then have $\overline{S} \oplus S \leq_d^p U$ via some reduction g . For each $z \in Z_x$, let

$$H_{x,z} = \{ \langle u_1, \dots, u_{n^\alpha} \rangle \mid (\forall j) u_j \in g(z[j] \cdot w_j^{x,z}) \}.$$

Let $r(n)$ be a polynomial bounding the run time of g on inputs of the form $z[j] \cdot w_j^{x,z}$, where $|x| = n$. Define

$$B_n = \{ \langle u_1, \dots, u_{n^\alpha} \rangle \mid (\forall j) u_j \in U_{\leq r(n)} \}.$$

Then we have

$$x \in A \iff (\exists z \in Z_x)(\exists y \in H_{x,z})y \in B_n.$$

Define an NPMV function N that on input x chooses some $z \in Z_x$ and tuple $y \in H_{x,z}$ and outputs y . Then N is an NP-reduction of A to the family $(B_n \mid n \geq 0)$.

Let $\delta = (1/s - \alpha)/2$. Then since $U \in \text{SUBEXPD}$, $\|U_{\leq r(n)}\| \leq 2^{n^\delta}$ for sufficiently large n . This implies

$$\|B_n\| = \|U_{\leq r(n)}\|^{n^\alpha} \leq 2^{n^{\alpha+\delta}} = 2^{n^{(1/s)-\delta}}.$$

Lemma 3.2 applies to show $A \in \text{NP/poly}$. □

We now have the main result of this paper:

Theorem 3.9. *If $\text{coNP} \not\subseteq \text{NP/poly}$, then for all $\epsilon > 0$, every $\leq_{n^{1-\epsilon}\text{-T}}$ -hard set for NP is exponentially dense.*

Proof. Suppose that $\text{SAT} \leq_{n^{1-\epsilon}\text{-T}}^{\text{P}}$ -reduces to a subexponentially dense set. Then $\overline{\text{SAT}} \leq_{n^{1-\epsilon}\text{-T}}^{\text{P}}$ -reduces to the same set by inverting the reduction's answers. Moreover $\overline{\text{SAT}}$ has an AND-function of order $s = 1$. Theorem 3.8 applies to show $\text{coNP} \subseteq \text{NP/poly}$. □

In fact, we can show a slightly stronger result. Theorem 3.8 still holds if the Turing reduction uses nondeterminism:

Theorem 3.10. *Let A have an AND-function of order s and let $\alpha < 1/s$. If $A \in \text{NP}^{S[n^\alpha]}$ for some $S \in \text{SUBEXPD}$, then $A \in \text{NP/poly}$.*

Proof. We extend the proof of Theorem 3.8. Suppose $A = L(M^{S[n^\alpha]})$ where M is an NP machine running in time $t(n)$. For an input $x \in \{0, 1\}^n$, we can use any pair $\langle p, z \rangle$ where $p \in \{0, 1\}^{t(n)}$ and $z \in \{0, 1\}^{n^\alpha}$ to run M on input x . We use p to provide the nondeterministic choices and z to provide the query answers. In this computation M produces a sequence of queries

$w_0^{x,p,z}, \dots, w_{n^\alpha}^{x,p,z}$ and an accepting or rejecting decision. Let Z_x be the set of all $\langle p, z \rangle$ that cause M to accept x . Then we have $x \in A$ if and only if

$$(\exists \langle p, z \rangle \in Z_x)(\forall 1 \leq j \leq n^\alpha) S[w_j^{x,p,z}] = z[j].$$

The remainder of the proof carries through with z replaced by $\langle p, z \rangle$ throughout. \square

We obtain an extension of Theorem 3.10 to strong nondeterministic polynomial-time reductions.

Theorem 3.11. *If $\text{coNP} \not\subseteq \text{NP/poly}$, then for all $\epsilon > 0$, every $\leq_{n^{1-\epsilon}\text{-T}}^{\text{SNP}}$ -hard set for NP is exponentially dense.*

Proof. Suppose that S has subexponential density and is $\leq_{n^{1-\epsilon}\text{-T}}^{\text{SNP}}$ -hard for NP. Then $\overline{\text{SAT}} \leq_{n^{1-\epsilon}\text{-T}}^{\text{SNP}} S$, so $\overline{\text{SAT}} \in \text{NP}^{S[n^{1-\epsilon}]}$. Theorem 3.10 implies $\overline{\text{SAT}} \in \text{NP/poly}$. \square

All our results to this point are conditional. For an unconditional result we go to the $\tilde{\text{P}}\text{H}$ hierarchy, where $\tilde{\text{P}}$ means $n^{O(\log n)}$.

Theorem 3.12. *For all $\epsilon > 0$, every $\leq_{n^{1-\epsilon}\text{-T}}^{\text{P}}$ -hard set for $\Sigma_3^{\tilde{\text{P}}}$ is exponentially dense.*

Proof. First, we claim that $\Sigma_3^{\tilde{\text{P}}} \not\subseteq \text{NP/poly}$. This is similar to Kannan's proof that Σ_2^{P} does not have n^k -size circuits [6]. We can show that there is a set $H \in \Sigma_4^{\tilde{\text{P}}} - \text{NP/poly}$ by a direct counting argument. Then we consider two cases: if $\text{coNP} \not\subseteq \text{NP/poly}$, the claim holds immediately because $\text{coNP} \subseteq \Sigma_3^{\tilde{\text{P}}}$. Otherwise $\text{coNP} \subseteq \text{NP/poly}$ and we have $\text{PH} = \Sigma_3^{\text{P}}$ by Yap's theorem [12]. From this padding gives $\tilde{\text{P}}\text{H} = \Sigma_3^{\tilde{\text{P}}}$ and therefore $H \in \Sigma_3^{\tilde{\text{P}}}$.

There is a many-one complete set A for $\Sigma_3^{\tilde{\text{P}}}$ with an AND-function of order 1. Suppose that $A \leq_{n^{1-\epsilon}\text{-T}}^{\text{P}}$ -reduces to a set S of subexponential density. Theorem 3.8 implies $A \in \text{NP/poly}$, so $\Sigma_3^{\tilde{\text{P}}} \subseteq \text{NP/poly}$, a contradiction. \square

We remark that Theorem 3.12 also holds for conjunctive, disjunctive, and SNP $n^{1-\epsilon}$ -Turing reductions.

4 Instance Complexity

Let A be a set and let $t(n)$ be a time bound. A program p is *consistent* with A for all x , $p(x) \in \{0, 1, ?\}$, and whenever $p(x) \neq ?$, $p(x) = A(x)$. The *t -instance complexity* of x with respect to A , written $ic^t(x : A)$ is the length of a shortest program p such that

- p is consistent with A ,
- $p(x)$ halts within $t(|x|)$ steps, and
- $p(x) = A(x)$.

Formally, $p(x) = U(p, x)$ where U is an efficient universal machine. See [11] for more information on instance complexity.

Theorem 4.1. *Let A have an AND-function of order s , let $\alpha < 1/s$, and let q be a polynomial. If $ic^q(x : A) \leq n^\alpha$ for all but finitely many $x \in A$, then $A \in \text{NP/poly}$.*

Proof. For each n , let $B_n = \{p \mid p \text{ is consistent with } A \text{ and } |p| \leq n^\alpha\}$. Then $\|B_n\| \leq 2^{n^{\alpha+1}}$. Define an NPMV function N that on input x guesses a program p and outputs p if the program accepts x within $q(|x|)$ steps. Then N reduces A to the family $(B_n \mid n \geq 0)$, so Lemma 3.2 yields $A \in \text{NP/poly}$. \square

Corollary 4.2. *If $\text{NP} \not\subseteq \text{coNP/poly}$, then for every polynomial q and $\epsilon > 0$, there exist infinitely many $\phi \in \overline{\text{SAT}}$ with $ic^q(\phi : \text{SAT}) > |\phi|^{1-\epsilon}$.*

Corollary 4.2 should be contrasted with the result that if $\text{P} \neq \text{NP}$, then there are infinitely many ϕ with $ic^q(\phi : \text{SAT}) \geq c \log |\phi|$. With the stronger $\text{NP} \not\subseteq \text{coNP/poly}$ hypothesis, we get a nearly linear lower bound on the instance complexity of SAT instances. Since $ic^{t(n)}(\phi : \text{SAT}) \leq |\phi| + O(1)$ for $t(n) = O(n \log n)$, this bound is fairly tight.

We can also show that the lower bound holds for a large set of SAT instances. Our next theorem is an extension of Theorem 4.1 that accounts for the density of the hard instances.

Theorem 4.3. *Let A have an AND-function of order s , let $\alpha < 1/s$, and let q be a polynomial. Define $H = \{x \in A \mid ic^q(x : A) > |x|^\alpha\}$. If $\|H_{\leq n}\| \leq 2^{n^\alpha}$ for sufficiently large n , then $A \in \text{NP/poly}$.*

Proof. Let $P_n = \{p \mid p \text{ is consistent with } A \text{ and } |p| \leq n^\alpha\}$. We define B_n as the disjoint union of $H_{\leq n}$ and P_n :

$$B_n = 0H_{\leq n} \cup 1P_n.$$

Then $\|B_n\| \leq 2^{n^{\alpha+2}}$ for large n . Define an NPMV function N that on input x either

- (i) outputs $0x$, or
- (ii) guesses a program p and outputs $1p$ if p accepts x within $q(|x|)$ steps.

Then N reduces A to the family $(B_n \mid n \geq 0)$ and Lemma 3.2 implies $A \in \text{NP/poly}$. \square

Corollary 4.4. *Suppose $\text{NP} \not\subseteq \text{coNP/poly}$. Then for all $\epsilon > 0$ and polynomials q ,*

$$\|\{\phi \in \overline{\text{SAT}}_{\leq n} \mid \text{ic}^q(\phi : \text{SAT}) > |\phi|^{1-\epsilon}\}\| \geq 2^{n^{1-\epsilon}}$$

for infinitely many n .

Next we consider reductions to sets that have low instance complexity.

Theorem 4.5. *Let A have an AND-function of order s and let $\alpha < 1/s$. Let C be a set where for all $\delta > 0$, there is a polynomial r such that $\text{ic}^r(x : C) < |x|^\delta$ for all but finitely many x . If $A \leq_{n^\alpha - \text{T}}^{\text{P}} C$, then $A \in \text{NP/poly}$.*

Proof. Let M compute the reduction from A to C in $t(n)$ time. Let $\epsilon = [(1/s) - \alpha]/2$. Choose $\delta > 0$ so that $t(n)^\delta < n^\epsilon$ for sufficiently large n . There is a polynomial r such that $\text{ic}^r(x : C) < |x|^\delta$ for almost all x .

Let x have length n . We can assume that M makes exactly n^α queries on input x . Define an NP machine N that on input x simulates M . When M makes a query q_i , N does the following:

- (i) Guess a program p_i with $|p_i| < |q_i|^\delta$.
- (ii) Run p_i on input q_i , aborting the computation if it runs for more than $r(|q_i|)$ steps.
- (iii) If p_i produces a decision, use that as the answer for query q_i in the simulation of M .

(iv) If p_i was aborted or did not output a decision, N halts and outputs nothing.

If M accepts x at the end of this simulation, then N outputs the tuple $\langle p_1, \dots, p_{n^\alpha} \rangle$ of programs it guessed.

Each query q_i has $|q_i| \leq t(n)$. Then for sufficiently large n ,

$$\text{ic}^r(q_i : C) < |q_i|^\delta \leq t(n)^\delta < n^\epsilon.$$

Define

$$E_n = \{p \mid p \text{ is consistent with } C \text{ and } |p| < n^\epsilon\}$$

and

$$B_n = \{\langle p_1, \dots, p_{n^\alpha} \rangle \mid \text{each } p_i \in E_n\}.$$

Then $\|B_n\| \leq (2^{n^\epsilon})^{n^\alpha} = 2^{n^{(1/s)-\epsilon}}$ and N reduces A to the family $(B_n \mid n \geq 0)$. Lemma 3.2 now applies to show $A \in \text{NP/poly}$. \square

We can also extend Theorem 4.5 to consider the density of the hard instances.

Theorem 4.6. *Let A have an AND-function of order s and let $\alpha < 1/s$. Let C be a set where for all $\delta > 0$, there is a polynomial r such that the collection of hard instances*

$$H^{\delta,r} = \{x \mid \text{ic}^r(x : C) \geq n^\delta\}$$

has subexponential density. If $A \leq_{n^\alpha\text{-T}}^P C$, then $A \in \text{NP/poly}$.

Proof. Let M compute the reduction from A to C in $t(n)$ time. We assume that M makes exactly n^α queries. Let $\epsilon = [(1/s) - \alpha]/2$ and choose $\delta > 0$ such that $t(n)^\delta < n^\epsilon$ for large n . There is a polynomial r such that $H^{\delta,r}$ has subexponential density.

Let x have length n . Define an NP machine N that on input x simulates M . When M makes a query q_i , N nondeterministically chooses (I) or (II) below to answer the query:

- (I) Guess a bit b and use it as the answer for query q_i . Record $z_i = \langle b, q_i \rangle$.
- (II) (i) Guess a program p_i with $|p_i| < |q_i|^\delta$.
(ii) Run p_i on input q_i , aborting the computation if it runs for more than $r(|q_i|)$ steps.

- (iii) If p_i was aborted or did not output a decision, N halts and outputs nothing.
- (iv) If p_i produces a decision, use that as the answer for query q_i . Record $z_i = \langle \lambda, p_i \rangle$.

If M accepts x at the end of the simulation, then N outputs the tuple $\langle z_1, \dots, z_{n^\alpha} \rangle$.

We have $\|H_{\leq t(n)}^{\delta, r}\| < 2^{n^\epsilon}$ for sufficiently large n . Define

$$E_n = \{\langle \lambda, p \rangle \mid p \text{ is consistent with } C \text{ and } |p| < n^\epsilon\},$$

$$D_n = \{\langle 1, q \rangle \mid q \in H_{\leq t(n)}^{\delta, r} \cap C\} \cup \{\langle 0, q \rangle \mid q \in H_{\leq t(n)}^{\delta, r} \cap \overline{C}\},$$

and

$$B_n = \{\langle z_1, \dots, z_{n^\alpha} \rangle \mid \text{each } z_i \in D_n \cup E_n\}.$$

Then

$$\|B_n\| = \left(\|E_n\| + \|H_{\leq t(n)}^{\delta, r}\| \right)^{n^\alpha} \leq (2^{n^\epsilon+1})^{n^\alpha} \approx 2^{n^{(1/s)-\epsilon}}.$$

We apply Lemma 3.2 to obtain $A \in \text{NP/poly}$. □

Corollary 4.7. *Suppose that $\text{NP} \not\subseteq \text{coNP/poly}$ and let C be $\leq_{n^{1-\epsilon}\text{-T}}^{\text{P}}$ -hard for NP. There is a $\delta > 0$ such that for every polynomial r , the set*

$$\{x \mid \text{ic}^r(x : C) \geq |x|^\delta\}$$

has exponential density.

Just like Theorem 3.11 we can show that Corollary 4.7 also holds for strong nondeterministic polynomial-time reductions. Also, by following the line of argument in Theorem 3.12, we can obtain an absolute result for instance complexity in Σ_3^{P} -hard sets.

Acknowledgements. We thank Lance Fortnow and Rahul Santhanam for sharing a preliminary version of [3], and for useful discussions. We also thank Scott Aaronson, Steve Fenner, Kolya Vereshchagin, and John Rogers for interesting discussions.
