Determinism versus Nondeterminism with Arithmetic Tests and Computation

Miklós Ajtai

June 16, 2013

Abstract. For each natural number \( d \) we consider a finite structure \( M_d \) whose universe is the set of all 0, 1-sequence of length \( n = 2^d \), each representing a natural number in the set \( \{0, 1, \ldots, 2^n - 1\} \) in binary form. The operations included in the structure are the constants 0,1,2\(^n\), multiplication and addition modulo \( 2^n \), the unary function \( \min\{2^x, 2^n - 1\} \), the binary functions \( \lfloor x/y \rfloor \), \( \max(x, y) \), \( \min(x, y) \), and the boolean vector operations \( \land, \lor, \neg \) defined on 0,1 sequences of length \( n \) by performing the operations on all components simultaneously. These are essentially the arithmetic operations that can be performed on a RAM by a single instruction. We show that there exists a term (that is, an algebraic expression) \( F(x, y) \) built up from the mentioned operations, with the only free variables \( x, y \), such that for all terms \( G(y) \), which is also built up from the mentioned operations, the following holds. For infinitely many positive integers \( d \), there exists an \( a \in M_d \) such that the following two statements are not equivalent: (i) \( M_d \models \exists x, F(x, a) \), (ii) \( M_d \models G(a) = 0 \). In other words, the question whether an existential statement, depending on the parameter \( a \in M_d \) is true or not, cannot be decided by evaluating an algebraic expression at \( a \).

We also show that this theorem remains true if we include the operation \( \min\{x^y, 2^n - 1\} \) into the structure \( M_d \). A general theorem is proved as well which describes sufficient conditions for a set of operations on a sequence of structures \( K_d \), \( d = 1, 2, \ldots \) which guarantees that the analogue of the mentioned theorem holds for the structure \( K_d \) too.

1 Introduction

1.1 Motivation, historical background

One of the central questions of complexity theory is the comparison of the computational resources needed for deterministic and nondeterministic computation. Namely, assume that we want to find a 0,1-sequence satisfying a test \( T \). Is it true under some natural assumptions on the test and on the algorithm searching for \( x \), that to find \( x \) requires essentially more computation, than checking that a given \( x \) really satisfies \( T \). In the case when both the test and the searching algorithm must be performed in polynomial time (in the length of \( x \)) by a Turing machine, this leads to the \( P = NP \) question.
In this paper we consider the special case of this problem where both the test and the search consist of the evaluation of an algebraic expression. Assume that $S$ is an algebraic structure with the operations $s_1, s_2, \ldots, s_k$. For example, $S$ can be a field or a ring and $s_1, \ldots, s_k$ can be the field/ring operations. We also assume that the structure $S$ has a distinguished element (defined as the value of a 0-ary operation $s_i$ for some $i = 1, \ldots, k$) that we will denote by $0$. In the case of a field/ring, $0$ will be always the usual zero of the field/ring. Suppose further that $F(x, y)$ is an algebraic expression built up from the operations $s_1, \ldots, s_k$. Our search problem will depend on a parameter $a \in S$. If such an $a \in S$ is fixed, then we want to find $x \in S$ such that $F(x, a) = 0$. That is, the test $T$ consists of checking whether for a given $x$ we have $F(x, a) = 0$. We will say that the problem has an algebraic solution, if there exists an algebraic expression $G(y)$ built up from the operations $s_1, \ldots, s_k$ such that $G$ depends only on $F$, and for all $a \in S$ the following two statements are equivalent: (i) there exists an $x \in S$ with $F(x, a) = 0$, and (ii) $F(G(a), a) = 0$. In other words if the equation $F(x, a)$ has a solution in $x$ then $x = G(a)$ is such a solution.

Alternately we will also consider the problem of deciding whether the equation $F(x, a)$ has a solution in $S$. In this case we will say that the problem can be decided by an algebraic expression if there exists an algebraic expression $G(y)$ such that for all $a \in S$, the equation $F(x, a)$ has a solution in $x$ iff $G(a) = 0$.

Several classical problems of mathematics can be formulate in this framework. For example, if $S$ is the field of real numbers and $F(x, a) = x^2 - a$ then there is no $G(y)$ built up from the field operations so that for all $a \geq 0$, $x = G(a)$ is a solution of $F(x, a) = 0$. Indeed for a rational $a$ the value of $G(a)$ is also rational while e.g., for $a = 2$ all of the solutions, namely $\pm \sqrt{2}$, are irrational. This was proved already by Pythagoras.

A more difficult problem if $S$ is the field of complex numbers (or any other algebraically closed field), and the operations are the field operations and taking $k$th roots for each positive integer $k$. It is a consequence of Galois theory (see [6]) that there is an equation $F(x, a) = 0$ whose solution cannot be expressed by the given operation, so there is no algebraic expression $G(y)$ with the required properties. (Actually such an $F$ can be constructed without using the “taking $k$-th root” operations.) Another example of similar nature is the problem of finding the antiderivative of an elementary function. We do not describe here the structure $S$, we just note that the basic results, that is, the existence of an elementary function whose antiderivative is not an elementary function (see e.g., [11]), can be also expressed in the present framework.

In this paper we consider the analogue questions in finite structures which, apart from the ring operations also contain other operations on integers which are used as instructions in random access machines. For each positive integer $d$ we will consider a structure $M_d$ whose universe is the set $\{0, 1, \ldots, 2^n - 1\}$, where $n = 2^d$. An element $b$ of $M_d$ is a natural number but sometimes we will consider it as a 0, 1-sequence of length $n$, defined by the binary form of $b$. The operations on $M_d$ will be, roughly speaking, the operations that a random access machine would be able to perform on nonnegative integers represented by $n$ bits, where $n = 2^d$. Namely we assume that the operations of $M_d$ are the following: (1) addition and multiplication modulo $2^n$, (2) integer division, that is, the operation $[\frac{x}{y}]$, (3) max$(x, y)$, min$(x, y)$, (4) an operation $p(x)$ whose value is min$\{2^x, 2^n - 1\}$, (5) pointwise boolean negation, AND, OR, on 0, 1-sequences of length $n$. $M$ will denote a firstorder language which contains for each of these operations a function symbol with the corresponding arity. Referring to this language the described operations will be called
\( \mathcal{M} \)-operations. (The results of this paper remain valid if we include a binary operation \( \bar{p}(x, y) \) whose value is \( \min\{x^y, 2^n - 1\} \).)

The \( \mathcal{M} \)-operations that we have in addition to the ring operations, make the extension of the algebraic proofs on Galois theory to the structures \( \mathcal{M}_d \) impossible. In spite of that we will show in Theorem 1, that there exists an algebraic expression \( F(x, y) \) (built up from \( \mathcal{M} \)-operations) such that for all algebraic expression \( G(y) \), (also built up from \( \mathcal{M} \)-operations), there exist infinitely many positive integers \( d \) such that for a suitably chosen \( a \in \{0, 1, \ldots, 2^d - 1\} \), we have that the following two conditions are not equivalent: (i) \( F(x, a) \) has a solution \( x \in \mathcal{M}_d \), and (ii) \( G(a) = 0 \) in the structure \( \mathcal{M}_d \).

The proof shows only that statements (i) and (ii) are not equivalent for infinitely many positive integers \( d \), but it seems likely, that there exists an \( F \) such that for all sufficiently large integers \( d \) and a suitably chosen \( a \in \{0, 1, \ldots, 2^d - 1\} \) they are not equivalent.

The mentioned result is about deciding whether an equation \( F(x, a) = 0 \) has a solution. However it is easy to see that the result remains valid for the search problem as well.

Of course the set of \( \mathcal{M} \)-operations is somewhat arbitrary. We may want to know which other operations can be added to \( \mathcal{M} \) such that the mentioned theorem remains true. We prove a general theorem, Theorem 2 about a sequence of structures \( \mathcal{K}_d, d = 1, 2, \ldots \), with universe(\( \mathcal{K}_d \)) = \( \{0, 1, \ldots, 2^n - 1\} \), \( n = 2^d \) which describes conditions that are sufficient for an analogue of Theorem 1.

The proofs are based on a Gödel type diagonalization argument. Diagonalization has been used for the proof of several theorems about problems which are algorithmically undecidable. E.g., if \( S \) is the ring of integers and the operations are the ring operation, then the theorem of Matijasevic, Davis, Putnam, and Robinson about the unsolvability of diophantine equations (see [13], [9]), can be considered in some sense an infinite analogue of the present problem, and has been proved by the method of diagonalization.

We compare now our results to other theorems, where nonlinear lower bounds were given, or deterministic and nondeterministic computation were separated in general computational models. Some of these proofs were based on diagonalization arguments. In fact the high level structure of the present proof is very similar to the structures of the proofs given in [10], [14], or [12]. The technical details however are completely different.

For multi-tape turing machines linear time nondeterministic and deterministic computations were separated in [14] by Paul, Pippenger, Szemerédi, and Trotter in 1984. Their theorem and the present result are not comparable in the sense, that none of them follows from the other, since in the turing machine model longer bitwise computations can be done than in our RAM model with the given time limit, but the RAM model allows arithmetic operations e.g., multiplication, and division of \( n \) bit numbers, and it is not known whether these operations can be computed on a multitape turing machine in linear time. For uniform computational models where the working memory is smaller than the input, Fortnow gave nonlinear lower bounds in [12]. In a similar sense as in the case of [14] our results and the results of [12] are not comparable. The high level structures of the proofs in both [14] and [12] however are very close to the high level structure of the present proof. The argument which forms the high level structure of all of these proofs was used by Hopcroft, Paul, and Valiant (see [10]) in 1977. There are also nonlinear lower bounds for nonuniform models of computations see [2], [7], [8], but the results are also incomparable to the present ones and even the high level structures of the proofs are completely
We can say that the difference between these already existing lower bounds and the ones in the present paper is that they are based on different properties of the computational models. Both in the case of the turing machine model, and in the models with small working memory, a lower bound proof is possible because of the organization of the memory, which in the second case includes the input. In both cases there are restrictions on the structure/use of the memory that is the crucial property used in the proof. In contrast, our present proofs, are not based on properties of the memory structure or the memory access, but on properties of the set of arithmetic instructions. Therefore our results say something about the set of arithmetic operations multiplication, addition etc., which is used in the usual random access machines.

A counterexample. In the last section we show that our main result does not hold if we replace the operations in $M_d$ with arbitrary other operations. We show the following. Assume that a sequence of structures $M_n$, $n = 1, 2, \ldots$ are given with universe $\text{universe}(M_n) = \{0, 1, \ldots, 2^n - 1\}$, where each $M_n$ is an interpretation of a first-order language $L$ with equality and with a finite number of constant and functions symbols. We show that there exists an extension $L'$ of $L$ with a finite number of function symbols, and for each $n = 1, 2, \ldots$ there exists an interpretation $M_n'$ of $L'$ which is an extension of $M_n$ on the same universe, such that for all terms $F(x, y)$ of $L'$, there exists a term $G(y)$ of $L'$ with the property that for all sufficiently large $n \in \omega$, we have

$$M_n' \models \forall a, \left( G(a) = 0 \leftrightarrow \exists x, F(x, a) = 0 \right)$$

1.1.1 Further results

In this section we sketch some related results which are not proved in the present paper.

(i) The proof described in the present paper guarantees only the existence of an $F$, through an indirect argument, it does not tell how to get an explicit expression $F(x, y)$. In the case of the structures $M_d$ (but not for the generalizations $K_d$ described in Theorem 2), with some modification of the proof, that we do not describe in this paper, it is possible to give an explicit construction for $F$. This modified proof also extends the result for expressions $G(y)$ which may depend on $d$, provided that their lengths remain below $\ell(d)$, where $\ell(d)$ is an explicitly given slowly growing elementary function.

(ii) The theorem about $M_d$ can be reformulated in a way that we replace the terms $F(x, y)$, $G(y)$ by constant time computation on a RAM $R_d$, whose each register contains a 0, 1 sequence of length $n = 2^d$. It is easy to see that evaluating the terms $F(x, y)$ and $G(y)$ can be equivalently formulated by constant time computation on the RAM $R_d$, whose arithmetic instructions are the functions of the structures $M_d$. (E.g., we may eliminate the conditional instruction of a RAM as described in [4] and [3].) This way the result is that there exists a program $P$ which can run on $R_d$, for each sufficiently large $d$, such that the following conditions are satisfied: (a) If the program $P$, working on machine $R_d$, gets the $n$ bit words $x$ and $a$ as input, then, in constant time, $P$ gives a TRUE or FALSE answer, and (b) there exists no program $Q$ such that for all sufficiently large $d$, given an $n$-bit word $a$ as an input $Q$ is able to decide in constant time whether there exists an $x$ with $P(x, a) \equiv \text{TRUE}$.

In other words if both the test and the decision process is constant time computation on RAMs, then we cannot get a correct decision each time. Using the results mentioned in (i),
where the size of the term $G$ may grow with $d$ it is possible to prove the statement about the tests on RAMs even if $Q$ is allowed to use time $\ell(d)$, where $\ell(d)$ is slowly growing explicitly given elementary function, even if $P$ can use only constant time.

We will return to the questions described in (i) and (ii) in another paper, where we also show that there exists a term $F(x,y)$ over the structures $M_d$ such that the following problem of size $n = 2^d$ is NP-complete: “for a given $a \in M_d$ find an $x \in M_d$ such that $M_d \models F(x,a) = 0$”.

### 1.2 The formulation of the main result

**Notation.** 1. $\omega$ will denote the set of all natural numbers, that is $\omega = \{0,1,2,\ldots\}$. The natural number $n$ will be considered as the set of all natural numbers less than $n$, that is, $n = \{0,1,\ldots,n-1\}$.

2. $\text{coeff}_i(a,b)$ denotes the $i$th $b$-ary “bit” of $a$. More precisely, assume that $a,b \in \omega$, $b \geq 2$, and $a = \sum_{i=0}^{\infty} a_i b^i$, where for all $i = \omega$, $a_i \in \omega$. The integer $a_i$ will be denoted by $\text{coeff}_i(a,b)$.

3. The set of all functions defined on the set $A$ with values in the set $B$ will be denoted by $\text{func}(A,B)$. The set of all $k$-ary functions defined on the set $A$ with values in the set $B$ will be denoted by $\text{func}_k(A,B)$. If we say that $\varphi(x_0,\ldots,x_k)$ is a firstorder formula of a language $\mathcal{L}$ then we will always assume, unless we explicitly state otherwise, that all of the free variables of the formula are among the variables $x_0,\ldots,x_k$. A firstorder statement with this notation would be $\varphi()$. If we say that $\psi$ is a firstorder formula without indicating any of its variables then there is no restriction on the number of variables in $\psi$. We will use the same convention for indicating the free variables in terms as well.

**Definition.** If $M$ is an interpretation of the firstorder language $\mathcal{L}$ and $X$ is a relation, constant or function symbol of $\mathcal{L}$, then $(X)_M$ will denote the interpretation of $X$ in the structure $M$. We extend this notations for terms as well, that is, if $t(x_0,\ldots,x_k)$ is a term with the free variables $x_0,\ldots,x_k$, then $(t)_M$ will denote the $k$-ary function which is the interpretation of this term in $M$.

**Definition.** 1. $\mathcal{M}$ will denote a firstorder language with equation, which does not contain any other relation symbols, and contains the following function and constant symbols. (We consider constant symbols as 0-ary function symbols as well.)

- Constant symbols: $0, 1, -1, n$
- Unary function symbol: $\mathcal{N}, p$ ( $\mathcal{N}$ stands for negation, $p$ stands for “power”).
- Binary function symbols: $+, \times, p, \div$, max, min, $\cap$.

2. Assume that $d \in \omega = \{0,1,2,\ldots\}$ and $n = 2^d$. $M_d$ will denote the following interpretation of the language $\mathcal{M}$: $\text{universe}(M_d) = \{0,1,\ldots,2^n-1\} = 2^n$ and for all $x,y,z \in \text{universe}(M_d)$, 

$$(M_d \models + (x,y) = z) \text{iff } x + y \equiv z \mod 2^n,$$

$$(M_d \models \times (x,y) = z) \text{iff } xy \equiv z \mod 2^n,$$

$$(M_d \models p(x) = z) \text{iff } z = \min\{2^x, 2^n - 1\},$$

$$(M_d \models z = \div (x,y) \text{iff } z = \lfloor x/y \rfloor),$$

$$(M_d \models z = 0) \text{iff } z = 0,$$

$$(M_d \models z = 1) \text{iff } z = 1,$$

$$(M_d \models z = n) \text{iff } z = n,$$

$$(M_d \models z = -1) \text{iff } z = 2^n - 1,$$
We define another language $\bar{M}$ of the interpretation $\bar{M}$ of $\langle \bar{M}, \{p\} \rangle$ without relation symbols other than equality. (We will call the 0-ary function symbols constant.

We will say that $\bar{M}$ is a generalization of Theorem 1, however, we need some additional arguments in the proof of the Corollary. We will describe these extra steps during the proof of Theorem 1.

3. Motivated by the definition of the standard interpretations we will use the following notation as well when we use the functions symbols of $\bar{M}$: $+(x,y) = x + y$, $\times(x,y) = x \times y$, $p(x) = 2^x$, $\div(x,y) = x/y$. Generally we will use this notation only if it is clear from the context that we mean the function symbol interpreted in a structure $\bar{M}$, otherwise $x + y$, $xy$, $2^x$ retain their usual meaning as operations among real numbers. □

**Definition.** When we use the function symbols of $\bar{M}$ we will write $x - y$ for $x + (-1)y$ and $-y$ for $(-1)y$. □

**Definition.** 1. Assume that $\varphi(x)$, $\psi(x)$ are firstorder formulas of $\bar{M}$ with the only free variable $x$. We will say that $\varphi(x)$ and $\psi(x)$ are asymptotically equivalent with respect to the sequence $\langle \bar{M}_d \mid d \in \omega \rangle$, if for all sufficiently large integers $d$, we have $\bar{M}_d \models \forall x, \varphi(x) \leftrightarrow \psi(x)$.

2. Assume that $F(x,y)$ is a term of $\bar{M}$ with the only free variables $x,y$. We say that the existence of a solution of the equation $F(x,y) = 0$ in $x$ can be decided by a term of $\bar{M}$ with respect to $\langle \bar{M}_d \mid d \in \omega \rangle$, if there exists a term $G(y)$ of $\bar{M}$ with the only free variable $y$, such that the formulas $\exists x, F(x,y) = 0$ and $G(y) = 0$ are asymptotically equivalent with respect to the sequence $\langle \bar{M}_d \mid d \in \omega \rangle$. □

**Theorem 1** There exists a term $F(x,y)$ of $\bar{M}$ with the only free variables $x,y$, such that the existence of a solution of the equation $F(x,y) = 0$ in $x$ cannot be decided by a term of $\bar{M}$ with respect to $\langle \bar{M}_d \mid d \in \omega \rangle$.

**Definition.** We define another language $\bar{M}$ that we get from $\bar{M}$ by adding to it a new binary function symbol $\bar{p}$. $\bar{M}_d$ will denote the interpretation of $\bar{M}$ which is the extension of the interpretation $\bar{M}_d$ (with the same universe) defined by $\langle \bar{M}_d \models \bar{p}(x,y) = z \rangle$ iff $z = \min\{x^y, 2^n - 1\}$, where $n = 2^d$. □

**Corollary 1** Theorem 1 remains true if we substitute $\bar{M}$ for $\bar{M}$ and $\bar{M}_d$ for $\bar{M}_d$.

The proof of the Corollary is almost identical to the proof of Theorem 1. At a few places however we need some additional arguments in the proof of the Corollary. We will describe these extra steps during the proof of Theorem 1.

2 A generalization of Theorem 1

**Definition.** We will say that $K$ is a $K$-sequence if the following two conditions are satisfied:

(i) $K$ is a firstorder language with equality, with a finite number of function symbols, and without relation symbols other than equality. (We will call the 0-ary function symbols constant symbols as well.)
(ii) \( K = \langle K_d \mid d \in \omega \rangle \) is a sequence of interpretations of \( K \) with the property that for all \( d \in \omega \), \( \text{universe}(K_d) = 2^n \), where \( n = 2^d \). □

**Notation.** 1. For the sake of brevity we will frequently write \( a \in K_d \) instead of \( a \in \text{universe}(K_d) \).

2. If \( t \) is a term and \( R \) is a relation symbol of \( K \) then we will use the notation \( t^{(d)} = (t)^{K_d} \) and \( R^{(d)} = (R)^{K_d} \).

In the following we will define several properties of a \( K \)-sequence \( K = \langle K_d \mid d \in \omega \rangle \) which together will imply that an analogue of Theorem 1 holds for \( K \). The first two properties regularity and projectivity, ensures that each \( K_d \) contains enough function so that certain elementary arguments or constructions which are available in \( M_d \) can be carried out in \( K_d \) as well.

We will say that a \( K \)-sequence \( K_d, d \in \omega \) is regular if certain “basic” functions can be easily defined in \( K_d \). The expression “easily defined” means in certain cases that the functions are interpretations of suitably chosen terms of \( K \) while in other cases it means that the functions can be defined by firstorder formulas in the structure \( K_d \). The mentioned functions are, roughly speaking, (i) constant functions with values 0 and 1, (ii) boolean functions of two variables, (iii) characteristic function of the equality relation, (iv) all of the functions defined on \( \{0, 1, \ldots, i - 1\} \) with values in the same set, provided that \( d \) is sufficiently large with respect to \( i \), (v) a function for forming pairs, provided that \( d \) is sufficiently large compared to the elements of the pairs.

**Definition.** Assume that \( K = \langle K_d \mid d \in \omega \rangle \) is a \( K \)-sequence. We say that \( K \) is regular if \( K \) contains the constant symbols 0, 1 and the following conditions are satisfied:

1. For each sufficiently large \( d \in \omega \), \( (0)^{K_d} = 0 \), \( (1)^{K_d} = 1 \)

2. For each binary function \( f(x, y) \) defined on the set \( \{0, 1\} \) and with values in \( \{0, 1\} \), there exists a term \( t(x, y) \) of \( K \), such that for all \( a, b \in \{0, 1\} \) and for all sufficiently large \( d \in \omega \), we have \( K_d \models f(a, b) = t(a, b) \).

3. There exists a term \( \bar{t}(x, y) \) of \( K \), so that for all sufficiently large \( d \in \omega \) we have \( K_d \models \forall x, y, (x = y \rightarrow \bar{t}(x, y) = 0) \land (x \neq y \rightarrow \bar{t}(x, y) = 1) \).

4. For each \( k \in \omega \), there exists a firstorder formula \( \varphi(x_0, \ldots, x_{k-1}, y, z) \) of \( K \) such that for all \( i \in \omega \) and for each \( k \)-ary function \( f(x_0, \ldots, x_{k-1}) \in \text{func}_k(\{0, 1, \ldots, i - 1\}, \{0, 1, \ldots, i - 1\}) \), there exists a \( j \in \omega \), such that for all sufficiently large \( d \in \omega \) and for all \( a_0, \ldots, a_{k-1}, b \in i \) we have that \( f(a_0, \ldots, a_{k-1}) = b \) iff \( K_d \models \varphi(a_0, \ldots, a_{k-1}, b, j) \).

5. There exists a firstorder formula \( \kappa(x, y, z) \) of \( K \) with the following property. For each \( i, j \in \omega \) there exists \( k \in \omega \) such that for all sufficiently large \( d \in \omega \), \( K_d \models \forall x, y, \kappa(x, y, k) \leftrightarrow (x = i \land y = j) \). □

We define now another property of \( K \)-sequence a \( K = \langle K_d \mid d \in \omega \rangle \). If \( K \) has this property then the elements of the direct product of \( 2^c \) copies, of \( K_d \), can be encoded by single elements of \( K_{d+c} \) so that the encoding is done by a term of \( K \), and the projections of the direct product to its \( k \)th component can be defined by a firstorder formula \( \Gamma \) which contains \( k \) and \( c \) as parameters but otherwise the choice of \( \Gamma \) does not depend on \( k \) and \( c \).
In the following definition we assume that the free variables of a first order formula or a term are among those which are explicitly shown.

**Definition.** Assume that \( K = \langle K_d \mid d \in \omega \rangle \) is a \( \mathcal{K} \)-sequence. We say that \( K \) is projective if for all \( c \in \omega \) and \( k \in 2^c \), there exists a term \( \pi_{c,k} \) of \( \mathcal{K} \) so that the following conditions are satisfied.

1. for all \( c \in \omega \) there exists a term \( \tau_c \) of \( \mathcal{K} \) such that if \( d \in \omega \) is sufficiently large, and \( a_0, \ldots, a_{2^c-1} \in K_d \), then for all \( k = 0, 1, \ldots, 2^c-1 \), we have \( K_{d+c} \models \pi_{c,k}(\tau_c(a_0, \ldots, a_{2^c-1})) = a_k \).

2. There exists a first order formula \( \Gamma(x, y, z, w) \) of \( \mathcal{K} \) such that for all \( c \in \omega \) if \( d \in \omega \) is sufficiently large and \( k \in 2^c \) then

\[
K_{d+c} \models \forall x, y, \Gamma(x, y, c, k) \iff \pi_{c,k}(x) = y
\]

**Definition.** Assume that \( K = \langle K_d \mid d \in \omega \rangle \) is a \( \mathcal{K} \)-sequence. If \( K \) is both regular and projective then we will say that \( K \) is complete.

**Proposition 1** Assume that \( K^{(i)} = \langle K_d^{(i)} \mid d \in \omega \rangle \) is a \( \mathcal{K}^{(i)} \) sequence for \( i = 0, 1 \), and \( \mathcal{K}^{(0)} \subseteq \mathcal{K}^{(1)} \), that is, every symbol of \( K_0 \) is also a symbol of \( K_1 \). Suppose further that for all \( d \in \omega \), the restriction of the model \( K_d^{(1)} \) of the language \( \mathcal{K}^{(1)} \) to the language \( \mathcal{K}^{(0)} \) is the model \( K_d^{(0)} \). Then we have that if the \( \mathcal{K}^{(0)} \) sequence \( K^{(0)} \) is complete then the \( \mathcal{K}^{(1)} \)-sequence \( K^{(1)} \) is also complete.

Proof. By the definition of a \( \mathcal{K} \)-sequence we have that \( \text{universe}(K_d^{(0)}) = \text{universe}(K_d^{(1)}) \).

The assumptions of the proposition imply that every function which is defined by a term in \( K_d^{(0)} \) is also defined in \( K_d^{(1)} \) by the same term, and every function which is defined by a first order formula in \( K_d^{(0)} \) is also defined in \( K_d^{(1)} \) by the same first order formula. The definitions of regularity and projectivity require only the existence of certain functions defined in the various structures \( K_d, d \in \omega \), by terms or first order formulas. Since the restriction of \( K_d^{(1)} \) to \( \mathcal{K}^{(0)} \) is \( K_d^{(0)} \), the functions guaranteeing the regularity or projectivity of \( K^{(0)} \) will play the same role for \( K^{(1)} \).

Q.E.D. Proposition 1

In the generalization of Theorem 1 we will speak about a \( \mathcal{K} \) sequence \( K = \langle K_d \mid d \in \omega \rangle \) which is complete and in addition to that it must be “retrospective” and “predictive” in the sense to be defined below. These properties establish connections between \( K_d \) and \( K_{d+c} \), where \( c \) is an arbitrary constant. Namely if we think that we construct the sequence \( K_0, K_1, \ldots, K_d, \ldots \) in this order then retrospection means that when we have \( K_d \) we are able using the functions defined in \( K_d \) to “look back” at \( K_{d-c} \) and decide the values of the functions defined in \( K_{d-c} \). Predictivity, in a similar way means, that using only functions defined in \( K_d \), we will be able to “predict”, in some sense, what will be the values of the functions defined in \( K_{d+c} \).

The next definition describes the following property of a \( \mathcal{K} \) sequence \( K_d, d \in \omega \). Assume that a \( g \) is function in \( K_{d-1} \) which is an interpretation of a function symbol of \( \mathcal{K} \). Then, in the structure \( K_d \), \( g \) can be expressed by a term. If \( g \) is in \( K_{d-c} \), then in the structure \( K_d \), \( g \) can be expressed by a first order formula containing \( c \) as a parameter.

**Definition.** Assume that \( K = \langle K_d \mid d \in \omega \rangle \) is a \( \mathcal{K} \)-sequence. We say that \( K \) is retrospective if it satisfies the following two conditions:
(8) Let \( k \in \omega \) and let \( g \) be a \( k \)-ary function symbol of \( K \). Then there exists a term \( t(x_0, \ldots, x_{k-1}) \) of \( K \) such that if \( d \in \omega \) is sufficiently large and \( a_0, \ldots, a_{k-1}, b \in K_{d-1} \) then \( K_{d-1} \models g(a_0, \ldots, a_{k-1}) = b \) iff \( K_d \models t(a_0, \ldots, a_{k-1}) = b \).

(9) Let \( k \in \omega \) and let \( g \) be a \( k \)-ary function symbol of \( K \). Then there exists a first-order formula \( \varphi(x_0, \ldots, x_{k-1}, y, z) \) of \( K \) such that for all \( c \in \omega \), if \( d \in \omega \) is sufficiently large and \( a_0, \ldots, a_{k-1}, b \in K_{d-c} \) then

\[
(K_{d-c} \models g(a_0, \ldots, a_{k-1}) = b) \iff K_d \models \varphi(a_0, \ldots, a_{k-1}, b, c)
\]

\[\square\]

In the next definition we will consider \( K \)-sequences \( K_d, d \in \omega \), where in the structure \( K_d \) we are able to decide in a first-order way whether a function \( f \) which is defined on \( \text{universe}(K_{d+c}) \), and which is an interpretation of a function symbol of \( K \), takes a certain value or not. More precisely, we will consider only the case when the elements of \( K_{d+c} \) can be encoded by binary relations on \( K_d \) and the question whether the function \( f \) takes a value or not can be decided by a first-order formula over \( K_d \), using these relations. (E.g., it is well-known that the addition and multiplication of the structure \( M_d \) have this property.) As we said earlier, if we consider the sequence of structures \( K_d \) as if they were constructed in time \( d = 0, 1, \ldots \), then this property implies that at time \( d \) we will be able to predict the behavior of the functions that will be constructed at time \( d + c \).

**Definition.** Assume that \( K = \langle K_d \mid d \in \omega \rangle \) is a \( K \)-sequence. We say that \( K \) is predictive if the following condition is satisfied

(10) There exists a function assigning to each function symbol \( f(x_0, \ldots, x_{k-1}) \) of \( K \), (including the constant symbols for \( k = 0 \)), a first-order formula \( \Phi_f(x, y, z, Y_0, \ldots, Y_{k-1}) \) of \( K \), where \( x, y, z \) are free individual variables and \( Y_0, \ldots, Y_{k-1} \) are free binary relation variables, such that the following holds. For all \( c \in \omega \) if \( d \in \omega \) is sufficiently large then there exists a map \( \eta_{d,c} \) of \( \text{universe}(K_{d+c}) \) into the set of binary relations on \( \text{universe}(K_d) \) with the following properties:

(i) For each \( a, u, v \in K_d \), we have \( \eta_{d,c}(a)(u, v) \) iff “\( u = 0 \) and \( v = a \)”.

(ii) Suppose that \( f(x_0, \ldots, x_{k-1}) \) is a \( k \)-ary function symbol of \( K \), for some \( k = 0, 1, \ldots \) (including the constant symbols for \( k = 0 \)) and \( a_0, \ldots, a_{k-1} \in K_{d+c} \). Then for all \( u, v \in K_d \), \( \eta_{d,c}(f^{(d+c)}(a_0, \ldots, a_{k-1}))(u, v) \) iff \( K_d \models \Phi_f(u, v, c, \eta_{d,c}(a_0), \ldots, \eta_{d,c}(a_{k-1})) \), where \( f^{(d+c)} = (f)_{K_{d+c}} \). \[\square\]

**Definition.** 1. Assume that \( \varphi(x), \psi(x) \) are first-order formulas of \( M \) with the only free variable \( x \). We will say that \( \varphi(x) \) and \( \psi(x) \) are asymptotically equivalent with respect to the \( K \)-sequence \( (K_d \mid d \in \omega) \), iff for all sufficiently large integers \( d \), we have \( K_d \models \forall x. \varphi(x) \leftrightarrow \psi(x) \).

2. Suppose that \( K = \langle K_d, d \in \omega \rangle \) is a \( K \)-sequence. Assume further that \( F(x, y) \) is a term of \( K \) with the only free variables \( x, y \). We say that the existence of a solution of the equation \( F(x, y) = 0 \), in the unknown \( x \), can be decided by a term of \( K \), if there exists a term \( G(y) \) of \( K \) with the only free variable \( y \), such that the formulas \( \exists x, F(x, y) = 0 \) and \( G(y) = 0 \) are asymptotically equivalent with respect to \( K \). \[\square\]
Theorem 2 Assume that \( \mathcal{K} \) is a \( \mathcal{K} \)-sequence, such that \( \mathcal{K} \) is complete, retrospective, and predictive. Then there exists a term \( F(x, y) \) of \( \mathcal{K} \) with the only free variables \( x, y \), such that the existence of a solution of the equation \( F(x, y) = 0 \) in the unknown \( x \), cannot be decided by a term of \( \mathcal{K} \).

Sketch of the proof. Assume that the statement of the theorem is not true, namely it does not hold for the \( \mathcal{K} \)-sequence \( \mathcal{K} = \langle \mathcal{K}_d \mid d \in \omega \rangle \), that is, \( \mathcal{K} \) satisfies the assumptions of Theorem 2 and yet its conclusion does not hold. We will reach a contradiction by using Gödel’s method of constructing a firstorder formula \( \varphi \) which expresses the statement that \( \varphi \) is false. Let \( \text{Form}(\mathcal{K}, k) \) be the set of all firstorder formulas of \( \mathcal{K} \) with at most \( k \) free variables. We will show that there exists a function \( \rho \in \text{func}(\text{Form}(\mathcal{K}, 1), \omega) \) and a firstorder formula \( \psi(x, y) \) of \( \mathcal{K} \) with the following property.

(11) For all \( \varphi \in \text{Form}(\mathcal{K}, 1) \) if \( d \) is sufficiently large, then \( \mathcal{K}_d \models \forall x, \varphi(x) \leftrightarrow \psi(x, \rho(\varphi)) \)

This leads to a contradiction in the following way. Let \( \varphi_0(x) = \neg \psi(x, x) \). Then condition (11) with \( \varphi := \varphi_0 \) implies that for all sufficiently large \( d \) we have \( \mathcal{K}_d \models \forall x, \neg \psi(x, x) \leftrightarrow \psi(x, \rho(\varphi_0)) \), and therefore \( \mathcal{K}_d \models \psi(\rho(\varphi_0), \rho(\varphi_0)) \leftrightarrow \neg \psi(\rho(\varphi_0), \rho(\varphi_0)) \) which is a contradiction. Note that in this argument we did not assume anything about the computability or definability of \( \rho \). (Otherwise \( \rho(\varphi) \) plays the role of the Gödel number of the formula \( \varphi \).)

To get the formula \( \psi \) and the function \( \rho \) we start with an arbitrary \( \varphi(x) \in \text{Form}(\mathcal{K}, 1) \). First we note that we may assume that if the formula \( \varphi(x) \) is in prenex form then its propositional part is of the form \( t(x) = 0 \) where \( t \) is a term. Since \( \mathcal{K} \) is regular, conditions (2) and (3) of the definition of regularity implies that \( \varphi \) can be easily transformed into this form.

Our plan is the following. First, instead of expressing the truth value of \( \varphi \) in the structure \( \mathcal{K}_d \), we express it in a larger structure \( \mathcal{K}_{d+c} \) where \( c \) is a constant. More precisely we will show (in Lemma 4) that:

(12) If Theorem 2 does not hold for \( \mathcal{K}_d \), then there exists a term \( G(x, y) \) of \( \mathcal{K} \), and there exist functions \( s \in \text{func}(\text{Form}(\mathcal{K}, 1), \omega) \), \( h \in \text{func}(\omega, \omega) \) with the following property. For all natural numbers \( \ell \) and for all firstorder formulas \( \varphi(x) \) of \( \mathcal{K} \) with length at most \( \ell \) we have that for all sufficiently large \( d \in \omega \) and for all \( a \in \mathcal{K}_d \), \( \mathcal{K}_d \models \varphi(a) \iff \mathcal{K}_{d+h(\ell)} \models G(a, s(\varphi, \ell)) = 0 \)

In other words the truth value of \( \varphi(a), a \in \mathcal{K}_d \) can be decided in the larger structure \( \mathcal{K}_{d+h(\ell)} \) by evaluating a term. Although we have to use the structure \( \mathcal{K}_{d+h(\ell)} \) instead of the structure \( \mathcal{K}_d \), but if \( \varphi \) is fixed then \( h(\ell) \) is a constant (while we change \( d \)). For a fixed \( \varphi \), the parameter \( s(\varphi, \ell) \) in the expression \( G(a, s(\varphi, \ell)) \) is also a constant. These facts will imply that using the predictivity of the \( \mathcal{K} \)-sequence \( \mathcal{K} \) we will be able to express the truth value of \( \mathcal{K}_d \models \varphi(a) \) by a formula \( \psi(a, \rho(\varphi)) \), where \( \psi \) does not depend on \( \varphi \) and this leads to a contradiction as described earlier.

In the step when we get the formula \( \psi \) from the term \( G \), the predictivity of \( \mathcal{K} \) is used in the following way. The term \( G \) describes operations in the structure \( \mathcal{K}_{d+h(\ell)} \). The definition of predictivity implies that these operation can be performed in \( \mathcal{K}_d \) by firstorder formulas acting on the binary relations which represent the elements of \( \mathcal{K}_{d+h(\ell)} \) in \( \mathcal{K}_d \).
Now we sketch the proof of statement (12). We reach the required equivalent form of $K_d \models \varphi(a)$, for $a \in K_d$ in three steps.

Step 1. We show (Lemma 2) that if Theorem 2 does not hold for the $K$-sequence $K$, then there exists a term $G$ and a $c \in \omega$, both depending on $\varphi$, such that for all sufficiently large $d \in \omega$ we have that for all $a \in K_d$, $K_d \models \varphi(a)$ is equivalent to $K_{d+c} \models G_1(a) = 0$.

This statement is similar to (12) but it is not the same since the term $G$ may depend on $\varphi$. In fact the length of $G$ will grow with the length of $\varphi$ in the construction described in the proof of Step 1.

The proof of Step 1 is using the assumption that Theorem 2 is not true and therefore an existential statement of the type $\exists x, F(x, a) = 0$ is equivalent to a quantifier free statement of the form $G_1(a) = 0$. This suggests a process of quantifier elimination applied to the formula $\varphi$. To carry out the quantifier elimination we would need to eliminate quantifiers from statements of the type $\exists x, F(x, b_1, \ldots, b_k, a) = 0$ where $b_1, \ldots, b_k$ are fixed elements of $K_d$. In other words we would need our indirect assumption for equations with more than one parameters. We do not have such an assumption, but we can reduce the many parameters to a single parameter by considering the same statement not in $K_d$ but in $K_{d+c}$, where $c$ is sufficiently large with respect to $k$. In this structure the $k+1$ parameters can be encoded by a single parameter, so the indirect assumption can be used. (We need the completeness and retrospectivity of $K$ to prove the correctness of this step.)

Step 2. After Step 1 we have a statement of the type $K_d \models G(a) = 0$ (with $d:= d + c$) where the the term $G$ depends on $\varphi$, in particular it $G$ can be arbitrarily large since we used the indirect assumption in its construction, which does not provide any limit on its size. In this step we show that (see Lemma 3)

\[(13) \text{ There exists a firstorder formula } \xi(y, z) \text{ of } K \text{ so that if } K = (K_d \mid d \in \omega) \text{ is a } K\text{-sequence, then for each term } G(y) \text{ of } K, \text{ and for each sufficiently large } c \in \omega, \text{ there exists an } u_{c,G} \in \omega, \text{ with the property that for all sufficiently large } d \in \omega, \text{ and for all } a \in K_d, K_d \models G(a) = 0 \text{ is equivalent to } K_{d+c} \models \xi(y, u_{c,G}). \]

(We do not need the indirect assumption about $K$ in this statement.) The important point in this statement is that the formula $\xi(x, y)$ does not depend on the term $G$. The dependence on $G$ is only through a parameter of $\xi$. Applying Step 1 and then Step 2 we get that for all sufficiently large $d \in \omega$ and for all $a \in K_d$, $K_d \models \varphi(a)$ is equivalent to $K_{d+c_1} \models \xi(a, c_2)$, where $c_1$ and $c_2$ depends only on $\varphi$ (but not on $d$ or $a$).

The proof of statement (13) is based on the observation that the evaluation of a term can be described by existentially quantifying the values of its subterms. If the integer $c$ of statement (13) is sufficiently large with respect to $G$ (which is allowed) then such an existential quantification is possible in $K_{d+c}$.

Step 3. If we combine the first two steps we get, that for all sufficiently large $d \in \omega$, and for all $a \in K_d$, $K_d \models \varphi(a)$ is equivalent to $K_{d+c_1} \models \xi(a, c_2)$, where the firstorder formula $\xi$ does not depend on anything, and $c_1, c_2 \in \omega$ depend only on $\varphi$. Now we use the quantifier elimination, described in Step 1, again, and we get the term $G$ whose existence is claimed in statement (12). Since $\xi$ does not depend on $\varphi$ the term $G$, that we gain at the end of the elimination process, will not depend on it either, the dependence on $\varphi$ will be only through the parameters of $G$.

End of Sketch
2.1 Proof of Theorem 2

Definition. Assume that $K = \langle K_d \mid d \in \omega \rangle$ is a $\mathcal{K}$-sequence with respect to the language $\mathcal{K}$ and $k \in \omega$. We will say that a family of $k$-ary functions $f^{(d)} \in \text{func}_k(\text{universe}(K_d), \text{universe}(K_d))$, $d \in \omega$, is an external $K$ family. The external $K$ family of $k$-ary functions will be called a firstorder $K$ family of $k$-ary functions, if there exists a firstorder formula $\varphi(x_0, \ldots, x_{k-1}, y)$ of $\mathcal{K}$, whose free variables are among $x_0, \ldots, x_{k-1}, y$, such that for all sufficiently large $d \in \omega$, and for all $a_0, \ldots, a_{k-1}, b \in K_d$, we have $b = f(a_0, \ldots, a_{k-1})$ iff $K_d \models \varphi(a_0, \ldots, a_{k-1}, b)$.

The external $K$ family of $k$-ary functions will be called an internal $K$ family of $k$-ary functions, if there exists a term $t(x_0, \ldots, x_{k-1})$ of $\mathcal{K}$ with $k$ free variables, such that for all sufficiently large $d \in \omega$, and for all $a_0, \ldots, a_{k-1} \in K_d$ we have $t^{(d)}(a_0, \ldots, a_{k-1}) = f(a_0, \ldots, a_{k-1})$, where $t^{(d)} = (t)_K$. In this case the family of functions $f^{(d)}$ is called the family of functions induced by the term $t$. Sometimes we will say "$K$ firstorder-family" instead of "firstorder $K$ family of functions" "$K$ internal-family" instead of "internal $K$ family of functions", and "$K$ external-family" instead of "external $K$ family of functions". □

Remark. It is important in the definition of a firstorder $K$ family of function that in the formula $\varphi(x_0, \ldots, x_{k-1}, y)$ we do not allow any parameters. This makes the definition somewhat different from the usual definition of a firstorder definable function. □

Definition. 1. The set $A$ is a co-finite subset of the set $B$, or $A \subseteq B$ is co-finite, if $A \subseteq B$ and $B \backslash A$ is finite.

2. Assume $K = \langle K_d \mid d \in \omega \rangle$ is a $\mathcal{K}$-sequence, with respect to the language $\mathcal{K}$, $A \subseteq \omega$ is co-finite and for all $d \in A$, $R_1^{(d)}$, $R_2^{(d)}$ are $k$-ary relations on the set $\text{universe}(K_d)$. We will say that the family of relations $R_1 = \langle R_1^{(d)} \mid d \in A \rangle$ and $R_2 = \langle R_2^{(d)} \mid d \in A \rangle$ are asymptotically equivalent iff for all sufficiently large $d \in \omega$, we have that $\forall a_0, \ldots, a_{k-1} \in K_d, R_1^{(d)}(a_0, \ldots, a_{k-1}) \iff R_2^{(d)}(a_0, \ldots, a_{k-1})$. We will write $R_1 \sim R_2$ for "$R_1$ and $R_2$ are asymptotically equivalent".

3. Assume that $\varphi(x_0, \ldots, x_{k-1})$ is a firstorder formula of $\mathcal{K}$, $j \in \omega$. For all $d \in \omega$, $R_k^{(d)}[\varphi, j]$ will be the $k$-ary relation on $\text{universe}(K_d)$ defined by: "for all $a_0, \ldots, a_{k-1} \in K_d$, $(R_k^{(d)}[\varphi, j])(a_0, \ldots, a_{k-1})$ iff $K_{d+j} \models \varphi(a_0, \ldots, a_{k-1})\". The family of relations $\langle R_k^{(d)}[\varphi, j] \mid d \in \omega \rangle$ will be denoted by $R_k[\varphi, j]$. The relation $R_k^{(d)}[\varphi, 0]$ will be also denoted by $R_k^{(d)}[\varphi]$. The corresponding family of relations will be denoted by $R_k[\varphi]$.

4. If $F(x_0, \ldots, x_{k-1})$ is a term of $\mathcal{K}$ and $j \in \omega$, $n = 1, 2, \ldots$ then the relation $R_k^{(d)}[F(x_0, \ldots, x_{k-1})] = 0, j]$ will be denoted by $R_k^{(d)}[F, j]$, and for $j = 0$ by $R_k^{(d)}[F]$ as well. The corresponding families of relations will be denoted by $R_k[F, j]$ and $R_k[F]$.

Remark. According to these definitions the firstorder formulas $\varphi(x), \psi(x)$ are asymptotically equivalent iff the family of relations $R_1^{(d)}[\varphi], d \in \omega$ and $R_1^{(d)}[\psi], d \in \omega$ are asymptotically equivalent. □

Lemma 1 Assume that $K = \langle K_d \mid d \in \omega \rangle$ is a regular $\mathcal{K}$-sequence. For each propositional formula $P(x_1, \ldots, x_k)$ of $\mathcal{K}$, there exists a term $T(x_1, \ldots, x_k)$ of $\mathcal{K}$ so that for all sufficiently large $d \in \omega$, we have $K_d \models \forall x_1, \ldots, x_k, P(x_1, \ldots, x_k) \iff T(x_1, \ldots, x_k) = 0$ and $K_d \models \forall x_1, \ldots, x_k, \neg P(x_1, \ldots, x_k) \iff T(x_1, \ldots, x_k) = 1$. Consequently for each propositional
formula $P(x_1,\ldots,x_k)$ of $\mathcal{K}$ there exists a term $T(x_1,\ldots,x_k)$ of $\mathcal{K}$ so that the family of relations $R^{(d)}_k[P]$, $d \in \omega$ and $R^{(d)}_k[F]$, $d \in \omega$ are asymptotically equivalent.

Proof. Since the only relation symbol of the language $\mathcal{K}$ is the equality, we have that each atomic formula is of the form $t_1 = t_2$ where $t_1$ and $t_2$ are terms. By condition (3) of the definition of regularity $t_1 = t_2$ is equivalent to $\bar{t}(t_1,t_2) = 0$ and $\neg(t_1 = t_2)$ is equivalent to $\bar{t}(t_1,t_2) = 1$. Therefore using condition (2) for the various logical operations $\land, \lor, \neg$ etc. we can transform each propositional formula of $\mathcal{K}$ into a propositional formula into an equivalent propositional formula of the form $t = 0$, where $t$ is a term. Q.E.D.(Lemma 1)

*Remark.* If for an expression $x_0,\ldots,x_{k-1}$ we will sometimes write $x$ if the choice of $k$ is clear from the context.

**Proposition 2** Assume that for each $i = 0, 1, 2$, $\Phi_i$ is a firstorder formula with $k$ variables, $u,v \in \omega$, and we have $R_k[\Phi_0] \sim R_k[\Phi_1,u]$ and $R_k[\Phi_1] \sim R_k[\Phi_2,v]$. Then $R_k[\Phi_0] \sim R_k[\Phi_2,u+v]$.

Proof. Assume $\bar{x} \in (Kd)^k$, where $d$ is sufficiently large. Then $K_d \models \Phi_0(\bar{x})$ iff $K_{d+u} \models \Phi_1(\bar{x})$ and $K_{d+u} \models \Phi_1(\bar{x})$ iff $K_{d+u+v} \models \Phi_2(\bar{x})$ which implies our statement. Q.E.D.(Proposition 2)

**Remark.** If $F_i(\bar{x})$ is a term, then we may apply Proposition 2 with $\Phi_i(\bar{x}) := “F_i(\bar{x}) = 0”$. Therefore the proposition remains true if some of the $\Phi_i$s are not formulas but terms. $\Box$

**Proposition 3** Assume that $\mathcal{K} = \langle K_d \mid d \in \omega \rangle$ is a retrospective and projective $\mathcal{K}$-sequence. Then the following condition is satisfied.

(14) Let $k \in \omega$ and let $g^{(d)}$, $d \in \omega$ be a $k$-ary $\mathcal{K}$ internal-family of functions. Then there exists a $k+1$-ary $\mathcal{K}$ firstorder-family of functions $f^{(d)}$, $d \in \omega$ such that for all $c \in \omega$, for all sufficiently large $d \in \omega$, and for all $a_0,\ldots,a_{k-1} \in K_d$ we have $g^{(d)}(a_0,\ldots,a_{k-1}) = f^{(d+c)}(a_0,\ldots,a_{k-1},c)$.

Proof of Proposition 3. The statement of the proposition requires a proof since the terms involved in $g^{(d)}$ are defined in $K_d$, while the firstorder formula defining $f^{(d+c)}$ must be interpreted in $K_{d+c}$.

The firstorder formula $\varphi(x_0,\ldots,x_{k-1},y)$ defining the function $f^{(d+c)}$ will say that $y \in K_d$ and $g^{(d)}(x_0,\ldots,x_{k-1}) = y$. By condition (6) of the definition of projectivity, universe($K_d$) is the image of the map $\pi^{(d)}_{\leq 0}$. Therefore $b \in K_d$ iff $K_{d+c} \models \exists a, \Gamma(a,b,d,c,0)$, where $\Gamma$ is the firstorder formula from condition (7) from the definition of projectivity. Consequently $y \in K_d$ can be stated in $K_{d+c}$ in a firstorder way and by condition (9) by the definition of a retrospective $\mathcal{K}$-sequence, $g^{(d)}(x_0,\ldots,x_{k-1}) = y$ can be also defined in a firstorder way in $K_{d+c}$. (We need the firstorder formula expressing $y \in K_d$, since the formula guaranteed by condition (9) speaks only about the elements of $K_d$ and not of $K_{d+c}$.) Q.E.D.(Proposition 3)

**Proposition 4** Assume that $\mathcal{K} = \langle K_d \mid d \in \omega \rangle$ is a retrospective and projective $\mathcal{K}$-sequence. Then the following condition is satisfied.

(15) Let $k \in \omega$ and let $g(x_0,\ldots,x_{k-1})$ be a term of $\mathcal{K}$ with the only free variables $x_0,\ldots,x_{k-1}$. Then for all $c \in \omega$ there exists a term $h_{g,c}(x_0,\ldots,x_{k-1})$ of $\mathcal{K}$ with the only free variables $x_0,\ldots,x_{k-1}$ such that for all sufficiently large $d \in \omega$, and for all $a_0,\ldots,a_{k-1} \in K_d$ we have $g^{(d)}(a_0,\ldots,a_{k-1}) = h_{g,c}^{(d+c)}(a_0,\ldots,a_{k-1})$. 

13
Proof. We prove the proposition by induction on $c$. For $c = 1$ the statement of the proposition follows from condition (8) from the definition of retrospectivity. Assume that $c > 1$ and the proposition holds for all smaller values of $c$. We define $h_{g,c}$ by $h_{g,c}(x_0, \ldots, x_{k-1}) = h_{g,c-1,1}(x_0, \ldots, x_{k-1})$. Assume that $a_0, \ldots, a_{k-1} \in K_d \subseteq \text{universe}(K_{d+c-1})$. We have $h_{g,c}^{(d+c)}(a_0, \ldots, a_{k-1}) = h_{g,c-1,1}^{(d+c)}(a_0, \ldots, a_{k-1}) = h_{g,c-1}^{(d+c-1)}(a_0, \ldots, a_{k-1}) = g^{(d)}(a_0, \ldots, a_{k-1})$ as claimed in the conclusion of proposition. Q.E.D. (Proposition 4)

**Proposition 5** Assume that $K$ is a projective $K$-sequence and for all $c \in \omega$, $k \in 2^c$ let $\pi_{c,k}$ be the term whose existence is stated in the definition of projectivity. Then for all $c \in \omega$ and for all sufficiently large $d \in \omega$, $\pi_{c,k}^{(d+c)}$ is a map of $\text{universe}(K_{d+c})$ onto $\text{universe}(K_d)$. As a consequence, for each firstorder formula $Q_0x_0, \ldots, Q_{k-1}x_{k-1}, P(x_0, \ldots, x_{k-1})$ of $K$, where $Q_0, \ldots, Q_{k-1}$ are quantifiers, the following two statements are equivalent

(i) $K_{d+c} \models Q_0x_0, \ldots, Q_{k-1}x_{k-1}, P(\pi_{c,0}(x_0), \ldots, \pi_{c,k}(x_{k-1}))$

(ii) $Q_0a_0 \in K_d, \ldots, Q_{k-1}a_{k-1} \in K_d, K_{d+c} \models P(a_0, \ldots, a_{k-1})$

Proof. Condition (6) of the definition of projectivity implies that the image of $\pi_{c,k}^{(d)}$ is $K_d$. (For the conclusions given in (i) and (ii) it is enough to use, for example, the map $\pi_{c,0}^{(d+c)}$.) Q.E.D. (Proposition 5)

**Proposition 6** Assume that $K = \langle K_d \mid d \in \omega \rangle$ is a $K$-sequence, $\langle f^{(d)} \mid d \in \omega \rangle$ is a $k$-ary $K$ internal-family of functions and for each $j = 0, 1, \ldots, k-1$, $\langle g_j^{(d)} \mid d \in \omega \rangle$ is an $l$-ary $K$ internal-family of functions. For each $d \in \omega$, we define an $l$-ary function $h^{(d)}$ on $\text{universe}(K_d)$ by

$$h^{(d)}(a_0, \ldots, a_{l-1}) = f^{(d)}(g_0^{(d)}(a_0, \ldots, a_{l-1}), \ldots, g_k^{(d)}(a_0, \ldots, a_{l-1}))$$

for all $a_0, \ldots, a_{k-1} \in \text{universe}(K_d)$. Then $h^{(d)}$ is an $l$-ary $K$ internal-family of functions.

Proof. We get the term inducing the family $h^{(d)}$, by substituting the terms inducing the families $g_j^{(d)}$ into the corresponding term for $f^{(d)}$. Q.E.D. (Proposition 6)

**Proposition 7** Assume that $K$ is a retrospective and projective $K$-sequence, and for all $c \in \omega$, $\tau_c$ is the term of $K$ whose existence was stated in condition (6) of the definition of projectivity. Suppose further that $F(x, y_0, \ldots, y_{k-1})$ is a term of $K$. Then for all $c \in \omega$ with $2^c \geq k$, there exists a term $G(x, z)$ of $K$ so that for all sufficiently large $d \in \omega$ and for all $a, b_0, \ldots, b_{k-1} \in K_d$ the following two statements are equivalent:

(i) $K_d \models F(a, b_0, \ldots, b_{k-1}) = 0$

(ii) $K_{d+c} \models G(a, \tau_c(b_0, \ldots, b_{k-1}, 0, \ldots, 0)) = 0$.

Proof. The term $G$ is defined by $G(x, y) = h_{F,c}(x, \pi_{c,0}(y), \pi_{c,1}(y), \ldots, \pi_{c,k-1}(y))$, where the term $h_{F,c}$ is defined in Proposition 4 and the term $\pi_{c,i}$ is from condition (7) of the definition of projectivity. Proposition 4 and the definition of projectivity imply that statements (i) and (ii) are equivalent. Q.E.D. (Proposition 7)

As we said earlier if Theorem 2 is not true then there is a possibility for quantifier elimination. In the next lemma we show that this really can be done with a firstorder formula $\varphi$ interpreted
in $K_d$, at the price of getting the equivalent quantifier free formula not in $K_d$ but in $K_{d+c}$, where
the equivalence is valid for all sufficiently large $d$, and $c$ depends only on $\varphi$.

**Definition.** Assume that $K = \langle K_d \mid d \in \omega \rangle$ is a complete, retrospective, and predictive $K$-sequence such that the conclusion of Theorem 2 does not hold for $K$. Then we will say that $K$ is a counterexample for Theorem 2. □

**Lemma 2** Assume that Theorem 2 does not hold and $K = \langle K_d \mid d \in \omega \rangle$ is a counterexample for Theorem 2. Then for each firstorder formula $\varphi(x_0, \ldots, x_{k-1})$ of $K$, there exist a
c = c_\varphi \in \omega$ and a term $G(x_0, \ldots, x_{k-1}) = G_\varphi(x_0, \ldots, x_{k-1})$ of $K$ such that, the family of
relations $R_k[\varphi(x_0, \ldots, x_{k-1})]$ and $R_k[G(x_0, \ldots, x_{k-1}), c]$ are asymptotically equivalent.

Proof. Assume that $\varphi(\bar{x})$ has the following prenex from $\varphi(x) \equiv Q_0z_0, \ldots, Q_{l-1}z_{l-1}P(\bar{z}, \bar{x})$,
where $Q_0, \ldots, Q_{l-1}$ are quantifiers and $P$ is a propositional formula. By Lemma 1 we may assume that $P$ is of the form $F(\bar{z}, \bar{x}) = 0$ for a term $F$ of $K$. We prove the lemma in this form by induction on $l$, and by always assuming that the inductive assumption holds for all values of $k$. For $l = 0$ the statement of the lemma trivially holds with $c = 0$, $G = F$. Assume now that the lemma is true for $l = l - 1$. Lemma 1 and condition (2) from the definition of a regular $K$-sequence implies that the statement of the lemma is equivalent to the same statement with $\varphi := \neg \varphi$, therefore we may assume that $Q_{l-1}$ is the quantifier $\exists$.

As we have noted earlier, Lemma 1 implies that there exists a term $F_1$ of $K$ so that for each sufficiently large $d$ and for each $a_0, \ldots, a_{l-2}, b_0, \ldots, b_{k-1} \in K_d$, we have that $K_d \models \exists z_{l-1}F_1(a_0, \ldots, a_{l-2}, z_{l-1}, b_0, \ldots, b_{k-1})$ is equivalent to $K_d \models F_1(\bar{a}, \bar{z}, \bar{b}) = 0$. By Proposition 7, there exists a $c_1 \in \omega$ and a term $G_1(\bar{x}, \bar{z})$ of $K$ so that for all sufficiently large $d \in \omega$ and for all $a_0, \ldots, a_{l-2}, b_0, \ldots, b_{k-1} \in K_d$, we have that $K_d \models F_1(\bar{a}, \bar{z}, \bar{b}) = 0$. By Lemma 1, we get that there exists a term $G_2$, such that for all sufficiently large $d \in \omega$ and for all $a_0, \ldots, a_{l-2}, b_0, \ldots, b_{k-1} \in K_d$ we have that $K_d \models G_1(z_{l-1}, a_0, \ldots, a_{l-2}, b_0, \ldots, b_{k-1}) = 0$. Using our assumption that Theorem 2 is not true with $F := G_1$, we get that there exists a term $G_2$, such that for all sufficiently large $d \in \omega$ and for all $a_0, \ldots, a_{l-2}, b_0, \ldots, b_{k-1} \in K_d$ we have that $K_d \models G_2(\tau_{c_1}(a_0, \ldots, a_{l-2}, b_0, \ldots, b_{k-1})) = 0$. Consequently, by using Proposition 5, we get that the statement $K_d \models Q_0z_0, \ldots, Q_{l-1}z_{l-2}, \exists z_{l-1}F_1(\bar{a}, \bar{z}, \bar{b})$ is equivalent to $K_d \models G_2(\tau_{c_1}(a_0, \ldots, a_{l-2}, b_0, \ldots, b_{k-1})) = 0$, which can be written in the form of $K_d \models \varphi_1(b_0, \ldots, b_{k-1})$, where $\varphi_1$ is a firstorder formula of $K$ containing $l - 1$ quantifiers in its prenex form. Therefore we may apply the inductive assumption with $\varphi := \varphi_1$. We get that there exists a term $G$ of $K$ so that for all sufficiently large $d \in \omega$ and for all $b_0, \ldots, b_{k-1} \in K_d$ we have that $K_d \models G(b_0, \ldots, b_{k-1})$. Since this is true for all choices of $b_0, \ldots, b_{k-1} \in K_d$ we have that the family of re-
lations $\mathcal{R}_k[\varphi(x_0, \ldots, x_{k-1})]$ and $\mathcal{R}_k[G(x_0, \ldots, x_{k-1}), c_1 + c_2]$ are asymptotically equivalent. Q.E.D. (Lemma 2)

Our next goal is to express the relation $G(y) = 0$ in $K_d$, where $G$ is a term of $K$, with a firstorder formula $\xi(y, z)$ such that the dependence of $G$ will be attained by substituting a parameter for $z$ which depends on $G$. The formula $\xi(x, z)$ in itself will not depend on $G$. We will be able to do this if the formula $\xi$ is interpreted in $K_{d+1}$, where $c$ is sufficiently large with respect to $G$ (but it does not depend on $d$). We will get that for a suitably chosen $u_{c,G} \in \omega$, and for all sufficiently large $d \in \omega$, $\forall y \in K_d, K_d \models G(y) = 0$ iff $K_{d+c} \models \xi(y, u_{c,G})$, where the parameter $u_{c,G}$ depends only on $c$ and $G$. The importance of this is that we replaced an arbitrarily large term $G$ with a firstorder formula $\xi$ of fixed size. This is important since during the quantifier elimination described in Lemma 2 we have no control on the size of the term $G$. This is a consequence of the fact that in the proof of Lemma 2 we use the assumption that Theorem 2 is not true and this assumption implies the existence of a term but without any bound on its size.

In the following lemma the assumption “Theorem 2 does not hold” is not needed.

Lemma 3 There exists a firstorder formula $\xi(y, z)$ of $K$ so that if $K = \langle K_d \mid d \in \omega \rangle$ is a $K$-sequence then for each term $G(y)$ of $K$ and for each sufficiently large $c \in \omega$ there exists an $u_{c,G} \in \omega$ with the property that the family of relations $\mathcal{R}_1[G(y)]$ and $\mathcal{R}_1[\xi(y, u_{c,G}), c]$ are asymptotically equivalent.

Proof. We may assume that all of the function symbols of the language $K$ has the same arity $k$, since for each $l < k$, an $l$-ary function $f(x_0, \ldots, x_{l-1})$ can be considered as a $k$-ary function which does not depend on its last $k - l$ variables $x_k, \ldots, x_{k-l-1}$. We will consider the constant symbols also as $k$-ary function symbols. Assume that all of the function symbols of $K$, including the constant symbols, are $f_0, \ldots, f_{\nu-1}$.

$\lambda$ will denote the number of subterms of the term $G$. We claim that there exist functions $r \in \text{func}(\lambda, \nu), g \in \text{func}(\lambda \times k, \lambda)$ so that for all sufficiently large $d \in \omega$ and for all $a \in K_d$, the following two conditions are equivalent

(i) $K_d \models G(a) = 0$

(ii) There exists $b_0, \ldots, b_{\lambda-1} \in K_d$ so that $b_0 = a$, $b_{\lambda-1} = 0$, and for all $i = 1, \ldots, j$, $b_i = f_{\nu-1}^{(d)}(g_{i,0}, \ldots, g_{i,k-1})$.

We define the functions $r, g$ in the following way. Let $t_0, \ldots, t_{\lambda-1}$ be all of the subterms of $G(y)$, so that $t_0$ is the variable $y$, and $t_{\lambda-1}$ is the term $G$, and each subterm $t'$ comes later in the sequence than any of its proper subterms. We choose the functions $r$ and $g$ such that $t_i = f_r^{(d)}(t_g(i,0), \ldots, t_g(i,k-1))$ for $i = 1, \ldots, \lambda - 1$. This completes the definition of $r$ and $g$. Suppose now that condition (i) holds. Then we choose $b_i \in K_d$ so that $K_d \models b_i = t_i(a)$. The definitions of the functions $r$ and $g$ imply that condition (ii) is satisfied. Conversely assume that statement (ii) holds. Again by the definitions of the functions $r$ and $g$, the sequence $b_i$ gives the values of the terms of $t_i(a)$. Since $b_{\lambda-1} = 0$ we have $K_d \models G(a) = 0$.

Assume that $c \in \omega$ is sufficiently large. Our next task is to express condition (ii) by a firstorder formula in $K_{d+c}$. First we note that the regularity of the $K$-sequence $K$ implies that there exist firstorder formulas $\eta_0, \eta_1, \eta_2, \eta_3, \eta_4$ such that for each term $G(y)$ of $K$ there exists a natural number $u_{c,G}$ so that for all sufficiently large $d \in \omega$ the following requirements are met:

(a) for all $i \in \nu + 1$, $i = \nu$ iff $K_d \models \eta_0(i, u_{c,G})$
(b) for all $i \in \lambda + 1$, $i = \lambda$ iff $K_d \models \eta_1(i, u_{c,G})$
(c) for all $i \in \lambda, j \in \nu$, $r(i) = j$ iff $K_d \models \eta_2(i, j, u_{c,G})$
(d) for all $i \in \lambda, j \in k, l \in \lambda$, $g(i, j) = l$ iff $K_d \models \eta_3(i, j, l, u_{c,G})$
(e) for all $i \in c + 1, i = c$ iff $K_d \models \eta_4(i, u_{c,G})$

These requirements say that the numbers $\nu, \lambda$ and the functions $r, g$ must be definable in a firstorder way from the number $u_{c,G}$, which depends only on $c, G$ but not on $d$, by formulas, which do not depend on either $G$ or $d$. This means that we may speak about $\nu, \lambda, r$ and $g$ in the structure $K_{d+c}$ by a firstorder formula which does not depend on $G$ or $d$ if this firstorder formula contains $u_{c,G}$ as a parameter.

Condition (ii), that we want to express in $K_{d+1}$, states the existence of a sequence $b_0, \ldots, b_{\lambda-1} \in K_d$ with certain properties. We will encode such a sequence with a single element of $K_{d+c}$, so that, these properties will be expressible in a firstorder way. This will make it possible to state the existence of the sequence $b_0, \ldots, b_{\lambda-1}$ by a single existential quantification in $K_{d+c}$.

Since $c$ is sufficiently large with respect to $G$ we may assume that $2^c \geq \lambda$. Each sequence $b_0, \ldots, b_{\lambda-1} \in K_d$ will be represented by the element $w = \tau_c^{(d+c)}(b_0, \ldots, b_{\lambda-1}, 0, \ldots, 0) \in K_{d+c}$ where $\tau_c$ is the term whose existence is stated in the definition of projectivity.

The definition projectivity imply that there exists a firstorder formula $\eta_5$ of $K$ so that for all $i \in \lambda, b \in K_{d+c}$ we have $b = b_i$ iff $K_{d+c} \models \eta_5(w, b, i)$.

Finally we have to describe the equations $b_i = \mathcal{f}_{r(i)}(b_{g(i,0)}, \ldots, b_{g(i,k-1)})$ by a firstorder formula in $K_{d+c}$. K is retrospective, therefore condition (9) of the definition of a retrospective $K$-sequence implies that this is possible using $c$ as a parameter in the formula. Condition (e) of the definition of $u_{c,G}$ implies that $c$ is definable from $u_{c,G}$ by a firstorder formula. We got that there exists a firstorder formula $\xi(y, z)$ of $K$ such that for all $a \in K_d$ condition (ii) is satisfied iff $K_{d+c} \models \xi(a, u_{c,G})$. Since conditions (i) and (ii) are equivalent for each sufficiently large $d$ this implies the statement of the lemma. Q.E.D.(Lemma 3)

**Definition.** The firstorder formula $\xi$ whose existence is stated in Lemma 3 is not unique, but we assume that a choice for $\xi$ has been fixed. The integer $u_{c,G}$ defined in the lemma will have the properties described there with this choice of $\xi$. The smallest integer $c \in \omega$ which satisfies the requirements of the Lemma 3 with $\xi$ will be denoted by $c(G)$. □

**Definition.** Suppose that $L$ is a firstorder language and $k \in \omega$. Form($L, k$) will denote the set of all firstorder formulas of $L$ with at most $k$ free variables. □

**Lemma 4** Assume that Theorem 2 does not hold and $K = \langle K_d \mid d \in \omega \rangle$ is a counter example for Theorem 2. Then there exists a term $G(y, z)$ of $K$ and functions $h \in \text{func}(\omega, \omega)$, $s \in \text{func}(\text{Form}(K, 1) \times \omega, \omega)$ such that for all $\ell \in \omega$, and for all firstorder formulas $\phi(y)$ of $K$ with length($\phi$) $\leq \ell$, the families of relations $R_1[G(y, s(\phi, \ell)), h(\ell)]$ and $R_1[\phi(y)]$ are asymptotically equivalent.

**Remark.** This lemma states that the truth value of a firstorder formula $\phi(y)$ as a function of $y$, for all formulas $\phi(y)$ of length at most $\ell$, can be determined by evaluating a term $G(y, u)$ in $K_{d+t}$, where $G$ does not depend on anything, $v$ depends only on $\ell$ and $u$ depends only on $\ell$ and $\phi$. Therefore, in some sense, we reduced the question of determining the truth value of a
first-order formula to the evaluation of a term. On the other hand we have to do the evaluation of this term in a larger structure, than the one where the truth value of the formula is considered.

Proof of Lemma 4. Let $\xi(y, z)$ be the first-order formula whose existence was stated in Lemma 3. The binary term $G(y, z) = G_\xi(y, z)$ with the properties guaranteed by Lemma 2 will be also the term $G(y, z)$ whose existence is stated in the present lemma. Lemma 2, with $\varphi := \xi$, states the existence of an integer $c_\xi \in \omega$ that we will use later.

We have to define the functions $h$ and $s$. Recall that if $G$ is a term then $c(G)$ denotes the smallest $c \in \omega$ with the properties in Lemma 3. Let $c'' = \max\{c_\psi + c(G_\psi) \mid \psi \in \text{Form}(\mathcal{K}, 2) \land \text{length}(\psi) \leq \ell\}$, $c' = c'' - c_\varphi$, $h(\ell) = c'' + c_\xi$, and $s(\varphi, \ell) = u_{c', G_\varphi}$, where the $u_{c, G}$ is the integer whose existence is guaranteed by Lemma 3.

We prove now that for all $\ell \in \omega$, for all first-order formulas $\varphi(y)$ of $\mathcal{K}$ with $\text{length}(\varphi) \leq \ell$, for all sufficiently large $d \in \omega$, and for all $a \in \mathcal{K}_d$ we have

\[(16) \ \mathcal{K}_d \models \varphi(a) \iff \mathcal{K}_{d + h(\ell)} \models G(a, s(\varphi, \ell)) = 0.\]

According to Lemma 2, for all $a \in \mathcal{K}_d$, $\mathcal{K}_d \models \varphi(a) \iff \mathcal{K}_{d + c_\varphi} \models G(\varphi)(a)$. The definitions of $c''$ and $c'$ implies that $c' \geq c(G_\varphi)$. Therefore by Lemma 3 we have that for all $a \in \mathcal{K}_d$, $\mathcal{K}_{d + c_\varphi} \models G(\varphi)(a) \iff \mathcal{K}_{d + c_\varphi + c'} \models \xi(a, u_{c', G_\varphi}).$ Finally using Lemma 2 again with $k := 2$, $\varphi := \xi(x_0, x_1)$ we get that for all $a \in \mathcal{K}_d$, $\mathcal{K}_{d + c_\varphi + c'} \models \xi(a, u_{c', G_\varphi}) \iff \mathcal{K}_{d + c_\varphi + c' + c_\xi} \models G(a, u_{c', G_\varphi}).$ These equivalences together imply that for all $a \in \mathcal{K}_d$, $\mathcal{K}_d \models \varphi(a) \iff \mathcal{K}_{d + c_\varphi + c' + c_\xi} \models G(a, u_{c', G_\varphi})$, which by the definitions of $h$ and $s$ implies condition (16). Q.E.D.(Lemma 4)

Definition. A term $G(y, z)$ of $\mathcal{K}$ with the properties described in Lemma 4, will be called a universal term. We assume that for each universal term $G$ of $\mathcal{K}$ a pair of functions, $h, s$ is fixed with the properties given in Lemma 4. To indicate their dependency on $G$, we will denote these functions by $h_G, s_G$. □

Lemma 5 Assume that $\mathcal{K}$ is a predictive $\mathcal{K}$-sequence and $H(x_0, x_1)$ is a term of $\mathcal{K}$. Then there exists a first-order formula $\Psi_H(x_0, x_1, w)$ of $\mathcal{K}$ such that for all $c \in \omega$ the family of relations $\mathcal{R}_2[H(x_0, x_1), c]$ and $\mathcal{R}_2[\Psi_H(x_0, x_1, c)]$ are asymptotically equivalent.

Proof. We will associate with each binary term $t(x_0, x_1)$ of $\mathcal{K}$ a first-order formula $\Lambda_t(u, v, w, y_0, y_1)$. We want to define $\Lambda_t$ such that for each fixed $c \in \omega$, if $d \in \omega$ is sufficiently large, then

\[(17) \ \text{for each fixed } a_0, a_1, p, q \in \mathcal{K}_d, (\eta_{d,c}(t(a_0, a_1)))(p, q) \iff \mathcal{K}_d \models \Lambda_t(p, q, c, a_0, a_1),\]

where $\eta_{d,c}$ is the map described in the definition of predictivity.

We define $\Lambda_t$ by recursion of the depth (maximal number of nested function symbols) of the term $t(x_0, x_1)$.

Assume first that $t(x_0, x_1)$ is the variable $x_i$ for some $i \in \{0, 1\}$. In this case $\Lambda_t(u, v, w, y_0, y_1)$ is the formula $u = 0 \land v = y_i$. Property (10)/(i) of the definition of a predictive $\mathcal{K}$-sequence implies that condition (17) is satisfied.
Suppose now that $t$ is an individual constant symbol. Then $\Lambda_t(u, v, w, y_0, y_1) \equiv \Phi_t(u, v, w)$, where the firstorder formula $\Phi_t$ is defined in the definition of predictivity. Property (10)/(ii) of the definition of predictivity implies that $\Lambda_t$ satisfies condition (17).

Let $t(x_0, x_1)$ be a term of the form $f(t_0, \ldots, t_{k-1})$, so that $\Lambda_t$, $i = 0, 1, \ldots, k - 1$ has been already defined and it satisfies condition (17). $\Lambda_t$ is defined by $\Lambda(u, v, w, y_0, y_1) \equiv \Phi(u, v, w, \Lambda_0(u, v, w, y_0, y_1), \ldots, \Lambda_{k-1}(u, v, w, y_0, y_1))$. Our inductive assumption implies that for all $i = 0, 1, \ldots, i - 1$ condition (17) is satisfied by $t := t_i$. Therefore property (10)/(ii) of the definition of predictivity implies that $\Lambda_t$ satisfies condition (17) as well.

Finally we define the firstorder formula $\Psi_H(x_0, x_1, w)$ by $\Psi_H(x_0, x_1, w) \equiv \forall u, v, \Lambda_H(u, v, w, x_0, x_1) \iff (u = 0 \land v = 0)$.

Let $H = (H)_{K_{d+c}}$. Condition (17) implies that for all $a_0, a_1 \in K_d$, $K_d \models \Psi_H(a_0, a_1, c)$ is equivalent to the statement that “for all $u, v \in K_d$, $(\eta_{d,c}(H(a_0, a_1)))(u, v)$ iff $(\eta_{d,c}(0))(u, v)$” and since the map $\eta_{d,c}$ is one-to-one, this is equivalent to the statement $H(a_0, a_1) = 0$. We got that if $c \in \omega$ is fixed then for all sufficiently large $d \in \omega$ and for all for all $a_0, a_1 \in K_d$, the following two statements are equivalent: $K_d \models \Psi_H(a_0, a_1, c)$ and $K_{d+c} \models H(a_0, a_1) = 0$ which is the statement of the lemma. Q.E.D.(Lemma 5)

Proof of Theorem 2. Let $\kappa(x, y, z)$ be the firstorder formula of $K$ whose existence is stated in condition (5) of the definition of a regular $K$-sequence. Assume that $G$ is a universal term. Let $\varphi$ be the formula $\forall u, v, \kappa(u, v, y) \to \neg \Psi_G(u, v, y)$, where $\Psi_G$ is the formula whose existence is stated in Lemma 5. Let $\ell = \text{length}(\varphi)$, $w = s_G(\varphi, \ell)$, and $c = h_G(\ell)$. By condition (5) of the definition of a regular $K$-sequence there exists an $r \in \omega$ such that for all sufficiently large $d \in \omega$ we have $K_d \models \forall x, y, \kappa(x, y, r) \to (x = w \land y = c)$. Let $d \in \omega$ be sufficiently large. Then by Lemma 4, $K_d \models \varphi(r)$ iff $K_{d+c} \models G(r, w) = 0$, where $w = s(\varphi, \ell)$. On the other hand using $\ell = \text{length}(\varphi) \geq \text{length}(\Psi_G)$ and Lemma 5 with $\varsigma := h(\ell)$ and $\varsigma := s(\varphi, \ell)$, we get the following sequence of equivalent statements: $K_d \models \varphi(r)$ iff $K_d \models \forall u, v, \kappa(u, v, r) \to \neg \Psi_G(u, v, r)$ iff $K_d \models \neg \Psi_G(w, c, r)$ iff $K_{d+c} \models \neg G(r, w) = 0$. Consequently $K_d \models \varphi(r)$ is equivalent to both $K_{d+c} \models G(r, w) = 0$ and $K_{d+c} \models \neg G(r, w) = 0$, that is, we reached a contradiction. Q.E.D.(Theorem 2)

## 3 Proof of Theorem 1

Proof of Theorem 1. Theorem 2 implies that it is sufficient to prove that $M = \langle M_d \mid d \in \omega \rangle$ is a complete, retrospective, and predictive $M$-sequence.

The definition of the language $M$ and universe($M_d$) = $2^d$, $d \in \omega$, implies that $M = \langle M_d \mid d \in \omega \rangle$ is an $M$-sequence. We show that it is complete, retrospective, and predictive. For the completeness of $M$ it is sufficient to prove that it is regular and projective.

$M$ is regular. Condition (1) describes the interpretation of the symbols $0$ and $1$ as described in the definition of $M_d$.

Condition (2). It is sufficient to show that the condition holds for $f(x, y) = \neg x$ and $f(x, y) = x \land y$ if we consider $0$ and $1$ as boolean values. For $f(x, y) = \neg x$ we have $t(x, y) = 1 - x$, and for $f(x, y) = x \land y$ we have $t(x, y) = xy$.

Condition (3). $\ell(x, y) = \min(1, x - y)$ meets our requirements.

Condition (4). Such a formula can be easily constructed by using the techniques of Gödel.
numbering, using only the function symbols \(0, 1, -1, +, \times, \max, \min\). (Not all of them are needed.)

Condition (5) We use the fact that the functions \(F_0(x) = x - \lfloor x/2 \rfloor^2, F_1(x) = \lfloor x/2 \rfloor^2 - F_0(x)\) has the property that for each \(y, z \in \omega\) there is an \(x \in \omega\) with \(F_0(x) = y\) and \(F_1(x) = z\). Indeed, if \(x = (y + z)^2 + y\), then \(F_0(x) = y\) and \(F_1(x) = z\). Based on this observation it is easy to see that the formula

\[\kappa(x, y, z) \equiv (\max(y, x) = x) \land (\max(z, x) = x) \land \exists u, (\max(u, x) = x) \land (\max(u^2, x) = x) \land (\max((u + 1)^2, x) \neq x) \land (y = x - u^2) \land (z = u - y)\]

satisfies the requirements of this condition.

\(M\) is retrospective. Conditions (8) and (9). We prove condition (9) in the strong form where the formula \(\varphi(x_0, \ldots, x_{k-1}, y, z)\) is of the form \(t(x_0, \ldots, x_{k-1}, z) = y\), where \(t\) is a term of \(\mathcal{K}\). Clearly this gives condition (8) with the term \(t(x_0, \ldots, x_{k-1}, 1)\).

We consider separately the various possible choices for the function symbol \(d\) and in each case we describe the required term \(t\). The term \(p(\frac{x+y}{d}, p(2, c))\) will be denoted by \(2^{\nu-d}n\).

- \(g = 1, t = 1; g = 0, t = 0; g = n, t = \frac{x+y}{d}; g = -1, t = 2^{\nu-d}n - 1; g = xy, t = x + y - \frac{x+y}{d}2^{\nu-d}n, g = x + y, t = x + y - \frac{x+y}{d}2^{\nu-d}n; g = p(y), t = \min(p(y), 2^{\nu-d}n - 1); g = \frac{x+y}{d}, t = \frac{x+y}{d}; g = \min(x, y), t = \min(x, y); g = \max(x, y), t = \max(x, y); g = x \cap y, t = x \cap y; g = \mathcal{N}(x), t = \mathcal{N}(x)\).

In the proof of the Corollary we will have the following: \(g = \bar{p}(x, y), t = \min(\bar{p}(x, y), 2^{\nu-d}n - 1)\)

Definition. Assume that \(a, m \in \omega, m > 0\). The least nonnegative residue of \(a \pmod{m}\) will be denoted by \(\text{res}(a, m)\).

**Proposition 8** Assume that \(u, v, a, b, m, i \in \omega, b \geq 2, a < b^m, i < m\). Then \(\text{res}(u, v) = u - v[\frac{u}{\nu}]\) and

\[\text{coeff}_{i}(a, b) = b^{-(m-1)} \text{res}\left(b^{m-1} \frac{a}{b^i}, b^m\right)\]

Proof. \(a = a_{m-1}b^{m-1} + \ldots + a_{i+1}b^{i+1} + a_i + a_{i-1}b^{i-1} + \ldots + a_0b^0\) where \(a_j = \text{coeff}_j(a, b)\) for \(j = 0, 1, \ldots, m-1\). Therefore \(a/b^i = a_{m-1}b^{m-1-i} + \ldots + a_{i+1}b^{i+1} + a_i + a_{i-1}b^{i-1} + \ldots + a_0b^0\) and consequently \(\lfloor a/b^i \rfloor = a_{m-1}b^{m-1-i} + \ldots + a_{i+1}b^{i+1} + a_i\). Multiplying both sides of the last equation by \(b^{m-1}\) we get \(b^{m-1}[a/b^i] = a_{m-1}b^{m-1-i+(m-1)} + \ldots + a_{i+1}b^{i+(m-1)} + a_i b^{m-1} = M\bar{b}^m + a_i b^{m-1}\), where \(M\) is an integer. The statement of the proposition is an immediate consequence of this equation.

**Q.E.D.** (Proposition 8)

\(M\) is projective. We will use in this proof that \(n^{d-c} = 2^n n^{d-c} = 2^n\). We want to define the terms \(\tau_c\) and \(\pi_{c,k}\) such that if \(c \in \omega, 2^c = \nu, k \in \{0, 1, \ldots, \nu - 1\}\), and \(d \in \omega, 2^d = n\) is sufficiently large then for all \(a_0, a_1, \ldots, a_{\nu-1} \in \mathbb{M}_d\) we have \(\tau_c(a_0, a_1, \ldots, a_{\nu-1}) = \sum_{k=0}^{\nu-1} a_k (2^d)^k\), and for each \(a \in \mathbb{M}_{d+c}, \pi_{c,k}(a) = \text{coeff}_k(a, 2^d)\). Clearly if this holds then the terms \(\tau_c, \pi_{c,k}\) satisfy condition (6) of the definition of projectivity.

The definition of \(\tau_c\) is simply the arithmetic expression \(\sum_{k=0}^{\nu-1} a_k (2^d)^k\) written with the function symbols of \(M\). Since \(\tau_c\) may depend on \(c\) we may express \(c\) in the form \(c = 1 + \ldots + 1\). All of the partial results in the expression \(\sum_{k=0}^{\nu-1} a_k (2^d)^k\) does not exceed the bound \(2^{d+c} - 1\) so the arithmetic operations occurring in it work the same way in \(\mathbb{M}_{d+c}\) as among the integers.
To define the term \( \pi_{c,k} \) it is sufficient to show that \( \text{coeff}_k(a, 2^n) \) can be computed by a term in \( M_{d+c} \). This is however an immediate consequence of Proposition 8 with \( a := a, b := 2^n, m := 2^c \). Here we used the fact that the operation \( x \times y \) in \( M_{d+c} \) is the least nonnegative residue of \( xy \) (computed by the multiplication among integers) modulo \( 2^{d+c} \).

The firstorder formula \( \Gamma \) of condition (7) describes the computation of \( \pi_{c,k} \) by the term defined above, but it uses \( c \) and \( k \) directly as parameters.

\( M \) is predictive. Assume that \( c \in \omega \) and \( d \) is sufficiently large. First we define the map \( \eta_{d,c} \) whose existence is required by the definition of predictivity. To make our notation more concise we will write \( \eta^{(a)}_{d,c} \) instead of \( \eta_{d,c}(a) \).

Assume that \( a \in M_{d+c}, 2^n = n, \nu = 2^c \). Let \( a_i = \text{coeff}_i(a, 2^n) \) for \( i = 0, 1, \ldots, \nu - 1 \). We define \( \eta_{d,c} \) by: “for all \( u, v \in M_d, \eta^{(a)}_{d,c}(u, v) \) iff \( u \in \nu \) and \( v = a_\nu \).” This definition implies that if \( a \in M_d \) then for all \( u, v \in M_d, \eta^{(a)}_{d,c}(u, v) \) iff \( u = 0 \) and \( v = a \), that is, our definition satisfies condition (10)/(i) from the definition of predictivity.

We define now the firstorder formula \( \Phi_f(x, y, z, Y_0, \ldots, Y_{k-1}) \) for each function symbol \( f \) of \( M \).

If \( f = c \) is a constant symbol of \( M \) then \( \Phi_c \equiv x = 0 \land y = c \). By the definition of \( \eta_{d,c} \), the formula \( \Phi_c \) satisfies condition (10)/(ii) from the definition of predictivity, for all constant symbols \( c \) of \( M \).

We will not use the relation \( \eta^{(a)}_{d,c} \) directly in the definition of \( \Phi_f \), for the remaining function symbols \( f \) of \( M \), but we first define another binary relation \( \xi^{(a)}_{d,c} \) on \( M_d \) and use this relation.

**Definition.** 1. For each positive integer \( k \) and \( u = (u_0, \ldots, u_{k-1}) \in (M_d)^k \), \( u_0 \) will denote the integer \( u_{k-1}n^{k-1} + u_{k-2}n^{k-2} + \ldots + u_1n + u_0 \).

2. Assume that \( R \) is a \( k \)-ary relation on the set \( n = \{0, 1, \ldots, n - 1\} \), where \( n = 2^d \). \( \text{integer}_k(R) \) will denote the integer \( \sum\{2^{\nu u} \mid u \in M_d^k \land R(u)\} \). Clearly \( R \rightarrow \text{integer}_k(R) \) is a one-to-one map from the set of all \( k \)-ary relation on \( n \) to the set of all natural numbers less then \( 2^{nk} \). If \( a \in [0, 2^{nk} - 1] \) is a natural number then the unique \( k \)-ary relation \( R \) on \( n \) with \( \text{integer}_k(R) = a \) will be denoted by \( \text{integer}^{-1}_k(R) \). \( \square \)

**Definition.** 1. Suppose that \( R \) is a \( k \)-ary relation on \( M_d \). We will say that the relation \( R \) is \( n \)-restricted if for all \( u = (u_0, \ldots, u_{k-1}) \in M_d^k \), \( R(u_0, \ldots, u_{k-1}) \) implies that for all \( i = 0, 1, \ldots, k - 1 \) with \( u_i \in n \).

2. Assume that \( d, c \) are positive integers and \( a < 2^{n^2} \). Then \( \xi^{(a)}_{d,c} \) is the unique binary relation on \( M_d \) which satisfies the following two conditions: (a) The relation \( \xi^{(a)}_{d,c} \) is \( n \)-restricted, and (b) \( \text{integer}_2(\xi^{(a)}_{d,c}) = a \). \( \square \)

**Proposition 9** There exists a firstorder formula \( \varphi(x, y, z) \) of \( M \) such that for all \( d \in \omega \) and for all \( a, b \in 2^{2d} \) and \( i \in 2^d \) we have that \( b = \text{coeff}_i(a, 2) \) iff \( M_d \models \varphi(a, b, i) \).

Proof. The statement of the proposition follows from Proposition 8. Q.E.D. (Proposition 9)

The following Proposition states that the relations \( \xi^{(a)}_{d,c} \) and \( \eta^{(a)}_{d,c} \) can be defined from each other in a firstorder way. It is important that for the definition of the value \( \xi^{(a)}_{d,c}(u, v) \) for a fixed pair \( u, v \) we may need the values \( \eta^{(a)}_{d,c}(x, y) \) for all \( x, y \in M_d \) and vice versa.
Proposition 10 There exist firstorder formulas $\Psi_i(x, y, z, Z)$, $i = 0, 1$, where $x, y, z$ are individual variables and $Z$ is a variable for a binary relation such that for all large $d \in \omega$, and for all $a \in M_{d+c}$ the following holds: $M_d \models \forall u, v, [\xi^{(a)}_{d,c}(u, v) \equiv \Psi_0(u, v, c, \eta^{(a)}_{d,c})]$ and $M_d \models \forall u, v, [\eta^{(a)}_{d,c}(u, v) \equiv \Psi_1(u, v, c, \xi^{(a)}_{d,c})]$

Proof. Assume $a \in 2^{2d+c}$ and $a = \sum_{i=0}^{2d} a_i(2^d)^i$. The formula $\Psi_i$ have to express the statement $u \leq v \land v \leq n \land \text{coeff}_u(a, 2) = 1$. $\text{coeff}_u(a, 2) = 1$ is equivalent to $\text{coeff}_v(a, 2) = 1$. Using the relation $\eta^{(a)}_{d,c}$ we can define $a_u$ in a firstorder way in $M_d$, namely $x = a_u$ iff $M_d \models \eta^{(a)}_{d,c}(u, x)$. If $a_u$ is given then, by Proposition 9, $\text{coeff}_v(a_u, 2)$ has a firstorder definition in $M_d$. This completes the definition of $\Psi_0$. In the firstorder formula $\Psi_1$ we have to define $a_u$ form its binary coefficients which can be done by using again Proposition 9. Q.E.D. (Proposition 10)

Proposition 10 implies that it is sufficient to prove that condition (10) of the definition of predictivity holds in the following modified form. (For the sake of notational simplicity we consider here $p$ and $N$ as a binary function symbols whose interpretation in each $M_d$ is a binary function which depends only in its first variable.)

(18) Suppose that $f$ is one of the function symbols $+, \times, p, \div, \max, \min, \land, N$ of $M$ then there exists a firstorder formula $\Phi_f(x, y, z, Y_0, Y_1)$ where $x, y, z$ are individual variables and $Y_0, Y_1$ are variables for binary relations such that for all $c \in \omega$, for all sufficiently large $d \in \omega$, and for all $a, b \in M_{d+c}$, and for all $u, v \in M_d$, $\xi^{(d+c)}(a, b)(u, v)$ is true iff $M_d \models \Phi_f(u, v, c, \xi^{(a)}_{d,c}, \xi^{(b)}_{d,c})$, where $f^{(d+c)} = (f)_{d+c}$.

In other words given the binary bits of $a, b \in 2^{2d+c}$, each by a binary relation on universe$(M_d)$, we have to define in $M_d$ in a firstorder way the binary bits of $a + b, ab, a \div b = [a/b], 2^a, \min(a, b), \max(a, b), a \land b, \text{and } N(a)$ where the operations are defined in the structure $M_{d+c}$. Since $a \land b$ and $N(a)$ are defined by bitwise operations this obviously can be easily accomplished for these two operations so from now on we consider only the remaining ones.

Using the function integer$^{-1}$ we can represent natural numbers from the interval $[0, 2^n - 1]$ by $k$-ary relations on $n$. Our next goal is to represent sequences of natural numbers by relation on $n$, (where we have a bound both on the length of the sequence and the sizes of its elements).

Definition. 1. The set of all sequences of length $i$, whose elements are from the set $A$ will be denoted by seq$(i, A)$. For example the set of all sequences of length $n^l$ whose elements are integers in the interval $[0, 2^n - 1]$ is seq$(n^l, 2^n)$.

2. Assume that $a = \langle a_0, \ldots, a_{j-1} \rangle \in \text{seq}(n^l, 2^n)$. We will represent this sequence by a $k + l$-ary relation $R^{(a)}$ on $n$ defined in the following way. For all $i \leq j - 1$, and for all $u_0, \ldots, u_{k-1}, v_0, \ldots, v_{l-1} \in n$, $R^{(a)}(u_0, \ldots, u_{k-1}, v_0, \ldots, v_{l-1})$ iff $(\text{integer}^{-1}_l)(a_i)(u_0, \ldots, u_{k-1})$, where $t = \sum_{i=0}^{l-1} v_i n^i$. Since in this representation the length of the sequence cannot be arbitrarily chosen it must be $n^l$, for some $l \in \omega$, we will call this representation a representation of the sequence without its length.

3. The definition above provides representation only for sequences with exactly $n^l$ elements for some natural number $l$. A sequence $a = \langle a_0, \ldots, a_{j-1} \rangle$ where $j < n^l$, $a_i \in [0, 2^n - 1]$
will be represented in the following way. We attach the number \(j\) as the first element to the sequence \(a\) and attach a sequence of 0s to its end, so that the total length of the sequence \(a' = \langle j, a_0, ..., a_{j-1}, 0, ..., 0 \rangle\) obtained this way is \(n'\). The representation of the sequence \(a\) together with its length will be the same as the representation of the sequence \(a'\) without its length, as defined earlier. In the following the representation of a sequence will always mean a representation of the sequence together with its length unless we explicitly state otherwise.

4. Assume that \(d\) is a positive integer and \(n = 2^d\). We will say that the set \(X\) is \(\mathbb{M}_d\)-representable if there exists natural numbers \(k, l\) such that either \(X = \{0, 1, ..., 2^n - 1\}\) or \(X = \text{seq}_n(n^l, 2^n)\). If \(X\) is an \(\mathbb{M}_d\) representable set and \(X = \{0, 1, ..., 2^{n-k} - 1\}\) then we define its weight by \(\text{weight}(X) = k\), if \(X = \text{seq}_n(n^l, 2^n)\) then we define its weight by \(\text{weight}(X) = k + l\).

If \(a \in X\), where \(X\) is an \(\mathbb{M}_d\) representable set, then \(\text{relation}_{a,n}\) will denote the \(k\)-ary or \(k+l\)-ary relation on \(n\) representing the element \(a\). □

We will consider now families of functions \(f^{(d)}\), \(d \in \omega\) so that for each \(d \in \omega\), \(f^{(d)} \in \text{func}(X^{(d)}, Y^{(d)})\) where both \(X^{(d)}\) and \(Y^{(d)}\) are \(\mathbb{M}_d\)-representable sets with weight less than \(w\) for a constant \(w\). We are interested in the case when such a family of functions can be defined by a firstorder formula in \(\mathbb{M}_d\) without using any parameters. The world “strongly” that we will use in the definition below refers to mentioned the lack of parameters.

**Definition.**

1. Assume that \(w_i \in \omega\) for \(i = 0, 1\) and for all \(d \in \omega\), \(A^{(d)}_i\) are \(\mathbb{M}_d\) representable sets of weight \(w_i\) for \(i = 0, 1\), and \(f^{(d)} \in \text{func}(A^{(d)}_0, A^{(d)}_1)\). We will say that the family of functions \(f^{(d)}\) is a strongly firstorder definable family function or a s.f.d.-family in \(\mathbb{M}\) if there exists a firstorder formula \(\Gamma(x_0, ..., x_{w1-1}, Z)\), where \(x_i, i = 0, 1, ..., w_1 - 1\) are individual variables and \(Z\) is a variable for \(k_d\)-ary relations such that for all sufficiently large \(d \in \omega\) and for all \(a \in A^{(d)}_0\) and \(b \in A^{(d)}_1\) with \(f(a) = b\), we have that for all \(u_0, ..., u_{w1-1} \in n\), \(\text{relation}_{b,n}(u_0, ..., u_{w1-1})\) iff \(\mathbb{M}_d \models \Gamma(u_0, ..., u_{w1-1}, \text{relation}_{a,n})\). □

We prove now that condition (18) is satisfied by each function symbol of \(\mathcal{M}\). As we mentioned already this statement trivially holds for the function symbols \(\cap\) and \(\mathcal{N}\) since the corresponding pointwise boolean operation can be executed on the relations representing the elements of \(\mathbb{M}_{d+c}\).

For the remaining operations we show now that the corresponding families of functions are strongly firstorder definable in \(\mathbb{M}\).

For \(f = \min\) and \(f = \max\) the statement is trivial since \(a \leq b\) iff \(\text{integer}_2^{-1}(a) \leq \text{integer}_2^{-1}(b)\) according to the lexicographic ordering which clearly can be defined in \(\mathbb{M}_d\) in a firstorder way.

The function symbol \(f = " + "\). If two integers are given in binary form each with \(m\) bits then the bits of their sum can be defined by a simple well-known constant depth circuit whose size is linear in \(m\). This circuit is defined in a uniform way which makes it possible to translate it into a firstorder formula interpreted in \(\mathbb{M}_d\). For later use we also consider now the case where we have to add a sequence of integers. This question has been also studied for circuits, and it is known that if we have at most \((\log m)^{c_0}\) integers with \(m^{c_1}\) binary bits then their sum can be computed by an unlimited fan-in boolean circuit with size \(m^{c_2}\) and depth \(c_3\), where \(c_2, c_3\) depend only on \(c_0\) and \(c_1\), see [1]. The construction of the circuit is uniform, in this case too, and can be translated into a firstorder formulas, that we need for our present purposes, over a structure containing the arithmetic operations. Firstorder formulas describing addition and multiplication in this sense were used in [5]. To make the paper more self-contained we prove
all the relevant facts about the firstorder definability of sums of sequences of integers.

**Definition.** If \( b \) is a finite sequence of integers then \( Sb \) will denote the sum of its elements. \( \square \)

**Lemma 6** Assume that \( c_0, c_1 \in \omega \). Then there exists a strongly firstorder definable family of functions \( f^{(d)}, d \in \omega \), such that for all sufficiently large \( d \) if \( n = 2^d, j \leq n^{c_0} \) and \( a \) is sequence of length \( j \), from elements of the set \( 2^{n^k} \), that is, \( a \in \text{seq}(j, 2^{n^k}) \), then \( Sa = f^{(d)}(a) \).

Proof or Lemma 6. During the proof we will use the notation \( n = 2^d, m = 2^n \), and we will always assume that \( d \) is sufficiently large with respect to \( c_0, c_1 \). We assume that \( \langle a_0, \ldots, a_{j-1} \rangle \in \text{seq}(j, 2^{n^k}) \) and we will define the binary bits of \( Sa \) using the bits of the integers \( a_i, a = 0, 1, \ldots, j - 1 \). While describing this definition which goes through several steps, we will indicate the reasons why the definition can be told in \( M \), defined by a firstorder formula in \( M \) we will always mean a firstorder formula of the type which was used in the definition of a strongly firstorder definable family of functions.

**Proposition 11** Lemma 6 holds with the additional assumption \( j = 2 \).

Proof of Proposition 11. We have \( a = a_0 + a_1 \) and we have to determine the binary bits of \( a_0 + a_1 \). Assume that \( a_0 = \sum_{i=0}^{n^k-1} \alpha_i 2^i, a_1 = \sum_{i=0}^{n^k-1} \beta_i 2^i \), and \( u + v = \sum_{i=0}^{n^k} \gamma_i 2^i \), where \( \alpha_i, \beta_i, \gamma_i \in \{0, 1\} \). Then for all \( i = 0, 1, \ldots, n^k \) we define \( \gamma_i \) in the following way. If there exists a \( t \in \{0, 1, \ldots, i - 1\} \) such that \( \alpha_t = \beta_t = 1 \) and for all \( k \), with \( t < k < i \), \( \alpha_k + \beta_k \geq 1 \), then \( \gamma_i = (\alpha_i + \beta_i) \). If such a \( t \) does not exists then \( \gamma_i = \alpha_i + \beta_i \).

This definition of \( \gamma_i \) can be stated in \( M \) in a firstorder way, since it requires quantification only on the set of integers \( \{0, 1, \ldots, n^{c_1}\} \), while \( \text{universe}(M_d) = 0, 1, \ldots, 2^n - 1 \). We have used the ordering of the set \( \{0, 1, \ldots, n^{c_1}\} \) which is also available since the operations \( \max(x, y), \min(x, y) \) define the natural ordering of \( \text{universe}(M_d) \). \( Q.E.D. \) (Proposition AR1.1)

**Proposition 12** Lemma 6 holds in the special case when \( j \leq \sqrt{n} \) and \( \max_{i=0}^{j-1} a_i \leq 2^{\sqrt{n}} \), where \( a = \langle a_0, \ldots, a_{j-1} \rangle \).

Let \( s_0 = 0, s_\nu = \sum_{i=0}^{\nu-1} a_i \), for \( \nu = 1, \ldots, j \). Each \( s_\nu \) has at most \( \log_2(\sum_{i=0}^{\nu-1} a_i) \leq \log_2(j \max_{i=0}^{j-1} a_i) \leq n^{\frac{1}{2}} + \log_2 j \leq 2n^{\frac{1}{2}} \) bits, so the total number of bits in the sequence \( s_1, \ldots, s_j \) is at most \( 2jn^{\frac{1}{2}} \leq 2n \). In \( M_d \) with a single existential quantifier we may talk about the existence of \( n \)-bits, so in \( M_d \) we can define the \( r \)th bit \( \gamma_r \) of \( Sa \) by saying that: \( \gamma_r = 1 \) if there exists a sequence \( s_0, \ldots, s_j \), and a \( b \in 2^n \), such that \( s_0 = 0, s_j = b \), for all \( i = 1, \ldots, j, s_j = a_{j-1} + s_j \) and the \( r \)th bit of \( b \) is 1. \( Q.E.D \) (Proposition 12)

**Proposition 13** Lemma 6 holds in the special case \( j \leq n^{1/2} \).

Proof of Proposition 13. Assume that \( a = \langle a_0, \ldots, a_{j-1} \rangle \) and for each \( i = 0, \ldots, j - 1, a_i = \sum_{s=0}^{l-1} \alpha_{s,i} 2^s \), where \( l = 2n^k \). We partition the interval \( [0, l - 1] \) into subintervals \( I_1, \ldots, I_r \) each of lengths \( n^{\frac{1}{2}} \). For \( \delta = 0, 1, \) let

\[
J_\delta = \bigcup \{ I_\nu \mid \nu \in [1, r] \land \nu \equiv \delta \pmod{2} \}
\]
For each \(i = 0, 1, \ldots, j-1\) we define two integers \(u_{0,i}, u_{1,i} \in [0, 2^j-1]\) by 
\[
u_{\delta,i} = \sum \{\alpha_{s,i}2^s \mid s \in J_\delta\}.
\] Proposition 12 implies that for \(\nu \in [0, l-1] \text{ and } \delta \in \{0, 1\}\), the integer \(v_{\delta}(\nu) = \sum \{\alpha_{s,i}2^s \mid i \in [0, l-1], \nu \in J_\delta \cap I_\nu\}\) is firstorder definable in \(M_d\). For fixed \(\nu\), \(\text{coeff}_s(v_{\delta}(\nu), 2) \neq 0\) implies that \(s \in I_\nu \cup I_{\nu+1}\), therefore for a fixed \(\delta\) if we add the numbers \(v_{\delta}(\nu)\), for example, for all even integers \(\nu\), there will be no “carry over” and so the binary bits of \(v_\delta\) are firstorder definable in \(M_d\). Finally by Proposition 6 the binary bits of their sum \(S\alpha = v_0 + v_1\) are also firstorder definable in \(M_d\). Q.E.D.(Proposition 13)

We may complete the proof of Lemma 6 in the following way. We may use Proposition 13 iteratively first adding blocks of size \(n^{\frac{1}{2}}\) in the sum \(\sum_{i=0}^{l-1} a_i\), and then repeating this for the resulting shorter sum etc. Q.E.D.(Lemma 6)

We prove condition (18) for \(f = \times\) in a more general form then needed, namely we will consider products with more than two factors. This will be useful in the proof of (18) for the function symbol \(\div\) and (in the proof of the Corollary) for function symbol \(\bar{p}\).

**Definition.** Assume that \(a = \langle a_0, a_1, \ldots, a_{j-1}\rangle\) is a sequence of integers. Then \(P\alpha\) will denote the number \(\prod_{i=0}^{j-1} a_i\). \(\square\)

**Definition.** Assume that \(\alpha(x), \beta(x)\) are functions defined on \(\omega\) with real values. We will say that the pair \(\langle \alpha(x), \beta(x)\rangle\) is acceptable if there exists a strongly firstorder definable family of functions \(f^{(d)}, d \in \omega\), such that for all sufficiently large integers \(d \in \omega\), for all nonnegative integers \(j \leq \alpha(d)\), and for all \(a \in \text{seq}(j, 2^{\beta(d)})\), we have \(P\alpha = f^{(d)}(a)\). \(\square\)

**Lemma 7** For each fixed \(c > 0, \epsilon > 0\) the pair \(\alpha(x) = x^c, \beta(x) = 2^{x^c + 2^{x^c-\epsilon}}\) is acceptable.

We prove the lemma by showing how can we create acceptable pairs of functions, possibly by using other acceptable pairs. These constructions are described in the following propositions. In the remaining of the paper if we say that a family of functions is firstorder definable we will mean that it is strongly firstorder definable.

**Proposition 14** Assume that \(\langle \alpha(x), \beta(x)\rangle\) is an acceptable pair and \(\bar{\alpha}(x), \bar{\beta}(x)\) are functions defined on \(\omega\) with real values so that for all sufficiently large \(d \in \omega\), \(\bar{\alpha}(d) \leq \alpha(d)\) and \(\bar{\beta}(d) \leq \beta(d)\). Then the pair \(\langle \bar{\alpha}(x), \bar{\beta}(x)\rangle\) is also acceptable.

Proof. The statement of the proposition is an immediate consequence of the definition of acceptability.

**Proposition 15** For all \(c > 0\) the following pair of function is acceptable: \(\alpha(x) = 2, \beta(x) = 2^{2^{2c}}\).

Proof. This is a consequence of Lemma 6, since the multiplication of two \(l\) bit integers can be performed as the addition of \(l\) integers each with \(2l\) bits if we follow the standard method of computing a product. Q.E.D.(Proposition 15)

**Proposition 16** Assume that \(\alpha, \beta\) are real valued functions defined on \(\omega\), \(c > 0\), and for all sufficiently large \(d \in \omega\) we have \((\alpha(d))^2 \beta(d) \leq cn\), where \(n = 2^d\). Then the pair \(\alpha(x), \beta(x)\) is acceptable.
Proof of Proposition 15. Assume that \( a = \langle a_0, \ldots, a_{j-1} \rangle \), and for all \( i = 0, 1, \ldots, j \) let \( p_i = \prod_{k=1}^{i} a_k \). Clearly \( p_0 = 1 \) and \( p_j = Pa \). The integer \( p_i \) has at most \( i\beta(d) \leq j\beta(d) \leq (\alpha(d)\beta(d)) \) binary bits. Therefore the total number of bits in the sequence \( \langle p_1, \ldots, p_j \rangle \) is at most \( j\alpha(d)\beta(d) \). This implies that we are able to speak about the existence of such a sequence \( \langle p_0, \ldots, p_j \rangle \) in a firstorder way. As a consequence, \( Pa = x \) will be equivalent to the following firstorder formula in \( M_d \) : “there exists a sequence \( p_0, \ldots, p_{j-1} \), such that \( p_0 = 0 \), and for all \( i = 1, \ldots, j \), \( p_i = a_{i-1}p_{i-1} \) and \( p_j = x \).” Q.E.D.

**Proposition 16**

Assume that \( \langle \alpha(x), \beta(x) \rangle \) is a pair of acceptable functions, \( c > 0 \) and \( t(x) \in \func(\omega, \omega) \), such that for all sufficiently large \( d \in \omega \) we have \( (t(d))^\alpha(d) \leq 2^{\alpha d} \). Then the pair \( \langle \alpha(x), t(x)\beta(x) \rangle \) is also acceptable.

**Proof.** Assume that \( d \in \omega \) is sufficiently large and \( a = \langle a_0, a_1, \ldots, a_{j-1} \rangle \in \seq(\alpha(d), t(d)\beta(d)) \). Let \( h = \lceil \beta(d) \rceil \). For all \( i = 0, 1, \ldots, j-1, k = 0, 1, \ldots, t(d) \) let \( b_{i,k} = \coeff_{k}(a_i, 2^h) \), that is, \( a_i = \sum_{k=0}^{t(d)-1} b_{i,k}2^{kh} \). Proposition 8 implies that the coefficients \( b_{i,k} \) are firstorder definable in \( M_d \).

If we compute the product \( \prod_{i=0}^{t(d)-1} a_i \) using \( a_i = \sum_{k=0}^{t(d)-1} b_{i,k}2^{kh} \) and distributivity then we get \( (t(d))^2 \leq (t(d))^\alpha(d) \leq n^c \) terms. Each of these terms is uniquely determined by a function \( \lambda \in \func(t(d), j) \), namely the term determined by such a function is \( \prod_{i=0}^{t(d)-1} \coeff_{\lambda(i)}(a_i, 2^h)2^{\lambda(i)h}. \) If we separate the powers of \( 2 \) in this product we can write it in the form of \( 2^h \sum_{i=0}^{t(d)-1} \lambda(i) \prod_{i=0}^{t(d)-1} \coeff_{\lambda(i)}(a, 2^h) \). We have \( \coeff_{\lambda(i)}(a, 2^h) \leq 2^h \leq 2^{\beta(d)} \), and \( j \leq \alpha(d) \), therefore the acceptability of the pair \( \langle \alpha(x), \beta(x) \rangle \) implies that \( \prod_{i=0}^{t(d)-1} \coeff_{\lambda(i)}(a, 2^h) \) of \( \lambda(i) \) is also firstorder definable in \( M_d \). By Lemma 6, \( \sum_{i=0}^{t(d)-1} \lambda(i) \) is also firstorder definable in \( M_d \). Since the total number of choices for the function \( \lambda(i) \) is at most \( n^c \), Lemma 6 implies that the sum is also firstorder definable in \( M_d \). Q.E.D.

**Proposition 17**

Assume that \( \langle \alpha(x), \beta(x) \rangle \) is a pair of acceptable functions, \( c > 0 \) and \( t(x) \in \func(\omega, \omega) \), such that for all sufficiently large \( d \in \omega \) we have \( (t(d))^\alpha(d) \leq 2^{\alpha d} \). Then the pair \( \langle \alpha(x), t(x)\beta(x) \rangle \) is also acceptable.

**Proof.** Assume that \( d \in \omega \) is sufficiently large and \( a = \langle a_0, a_1, \ldots, a_{j-1} \rangle \in \seq(\alpha(d), t(d)\beta(d)) \). Let \( h = \lceil \beta(d) \rceil \). For all \( i = 0, 1, \ldots, j-1, k = 0, 1, \ldots, t(d) \) let \( b_{i,k} = \coeff_{k}(a_i, 2^h) \), that is, \( a_i = \sum_{k=0}^{t(d)-1} b_{i,k}2^{kh} \). Proposition 8 implies that the coefficients \( b_{i,k} \) are firstorder definable in \( M_d \).

If we compute the product \( \prod_{i=0}^{t(d)-1} a_i \) using \( a_i = \sum_{k=0}^{t(d)-1} b_{i,k}2^{kh} \) and distributivity then we get \( (t(d))^2 \leq (t(d))^\alpha(d) \leq n^c \) terms. Each of these terms is uniquely determined by a function \( \lambda \in \func(t(d), j) \), namely the term determined by such a function is \( \prod_{i=0}^{t(d)-1} \coeff_{\lambda(i)}(a_i, 2^h)2^{\lambda(i)h}. \) If we separate the powers of \( 2 \) in this product we can write it in the form of \( 2^h \sum_{i=0}^{t(d)-1} \lambda(i) \prod_{i=0}^{t(d)-1} \coeff_{\lambda(i)}(a, 2^h) \). We have \( \coeff_{\lambda(i)}(a, 2^h) \leq 2^h \leq 2^{\beta(d)} \), and \( j \leq \alpha(d) \), therefore the acceptability of the pair \( \langle \alpha(x), \beta(x) \rangle \) implies that \( \prod_{i=0}^{t(d)-1} \coeff_{\lambda(i)}(a, 2^h) \) is firstorder definable in \( M_d \). By Lemma 6, \( \sum_{i=0}^{t(d)-1} \lambda(i) \) is also firstorder definable in \( M_d \). Since the total number of choices for the function \( \lambda(i) \) is at most \( n^c \), Lemma 6 implies that the sum is also firstorder definable in \( M_d \). Q.E.D.

**Proposition 18**

Assume that \( \alpha(x), \beta(x), \gamma(x) \) are functions defined on \( \omega \) with real values in the interval \( [1, \infty) \) and the pairs \( \langle \alpha(x), \beta(x)\gamma(x) \rangle \), \( \langle \gamma(x), \beta(x) \rangle \) are both acceptable. Then \( \langle \alpha(x)\gamma(x), \beta(x) \rangle \) is also acceptable.

**Proof.** Assume that \( d \in \omega \) is sufficiently large and \( a = \langle a_0, \ldots, a_{j-1} \rangle \in \seq(\alpha(d), \gamma(d), 2^{\beta(d)}) \). We partition the interval \( [0, j-1] \) into at most \( \alpha(d) \) intervals \( I_0, \ldots, I_{r-1} \) each of size at most \( \gamma(d) \). The pair \( \langle \gamma(x), \beta(x) \rangle \) is acceptable \( \gamma(x) \geq 1 \) therefore we can define the products \( P_k = \prod_{a \in I_k} a \), \( k = 0, 1, \ldots, r-1 \) in a firstorder way in \( M_d \). Moreover the value of each of these products will be at most \( (2^{\beta(d)})^{\gamma(d)} = 2^{\beta(d)\gamma(d)}. \) Since the pair \( \langle \alpha(x), \beta(x)\gamma(x) \rangle \) is acceptable we are also able to define \( \prod_{k=0}^{t(d)-1} P_k = Pa \) in a firstorder way in \( M_d \). Q.E.D.

**Proof of Lemma 7.** Assume that a \( \tau \in (0, 1) \) is given. We claim that

\begin{equation}
\text{(19) the pair } \langle x^\tau, 2^{x^1-x^1-\tau} \rangle \text{ is acceptable.}
\end{equation}

This is a consequence of Proposition 16 and of the fact that for all sufficiently large \( d \in \omega \), we have \( d^{2^d-2^{d^{1-\tau}}} \leq 2^d \). Suppose that for some integer \( s \) the pair \( \langle x^s, 2^{x+s^2x^{1-\tau}} \rangle \) is also acceptable.

We can apply Proposition 17 with \( \alpha(x):= x^{\tau}, \beta(x):= 2^{x+s^2x^{1-\tau}}, t(x):= 2^{x^{1-\tau}} \). Using the fact that \( (t(d))^\alpha(d) = 2^{d^2-d^{1-\tau}} = 2^d \), we get that the pair \( \langle x^{\tau}, 2^{x+s^2s^{1-\tau}} \rangle \) is also acceptable. With the help of this fact and condition (19), we can show by induction on \( s \), starting with \( s = -1 \), that the following holds:
(20) for all \( \tau \in (0, 1) \), and for all integers \( s \), the pair \((x^\tau, 2^{s+x^{1-\tau}})\) is acceptable.

We want to show that

(21) for all \( \tau \in (0, 1) \) and for all \( k, s \in \omega \) the pair \((x^{\tau+k}, 2^{s+x^{1-\tau}})\) is acceptable.

We prove this statement by induction on \( k \), where the inductive assumption is that the statement holds for a fixed \( k \), with every possible choices of \( \tau \) and \( s \). For \( k = 0 \) this is condition (20). Assume now that the statement holds for a fixed \( k \in \omega \).

We apply Proposition 18 with \( x := x^\tau + \frac{k}{2} \), \( \gamma(x) := x^\frac{1}{2} \) and \( \beta(x) := 2^{s+x^{1-\tau}} \). The first assumption of Proposition 18 is that the pair \( A_1 = (\alpha(x), \beta(x)\gamma(x)) = (x^\tau + \frac{k}{2}, x^\frac{1}{2} 2^{s+x^{1-\tau}}) \) is acceptable. Since \( x^{\tau} x^{1-\tau} + \frac{k}{2} \) \( \log_2 x \leq 2^{s+(s+1)x^{1-\tau}} \) the inductive assumption with \( s := s + 1 \) and Proposition 14 implies that the pair \( A_1 \) is acceptable.

The second assumption is that the pair \( A_2 = (\gamma(x), \beta(x)) = (x^\frac{1}{2}, 2^{s+x^{1-\tau}}) \) is acceptable. This follows directly from condition (20). Therefore by Proposition 18 the pair \((\alpha(x)\gamma(x), \beta(x)) = (x^\tau + \frac{k+1}{2}, 2^{s+x^{1-\tau}})\) is acceptable which completes the proof of (21). This and Proposition 14 together imply the statement of the lemma. Q.E.D.(Lemma 7)

**Proposition 19** For all \( \varepsilon > 0 \) there exists a family of functions \( f(d), d \in \omega \), such that, for all sufficiently large \( d \in \omega \) if \( a = \langle a_0, a_1 \rangle \in \text{seq}(2, 2^{d^d+d^{d-\varepsilon}}) \), then \( a_0 a_1 = f(d)(a) \).

Proof. The proposition is a special case of Lemma 7.

Using Proposition 19 we can show that condition (18) is satisfied by \( f = \chi \). Since for each fixed \( c > 0 \) if \( d \) is sufficiently large then \( d + d^\frac{1}{2} > d + c \), we get that multiplication in \( M_{d+c} \) can be defined in \( M_d \) in the sense of (18). This completes the proof of (18) for \( f = \chi \).

**Proposition 20** For all \( c > 1, c' > 1 \), there exists a strongly firstorder definable family of functions \( f(d), d \in \omega \), such that for all sufficiently large \( d \in \omega \), if \( a = \langle a_0, \ldots, a_{j-1} \rangle \) is a sequence of natural numbers such that \( a_i \leq 2^c \) for all \( i = 0, 1, \ldots, j-1 \) and \( c' \leq 2^{c'd} \), then \( Pa = f(d)(a) \).

Proof. Let \( p_i = \prod_{s=0}^{i-1} a_s \). Clearly \( p_0 = 1 \) and \( p_j = Pa \). The number of binary bits in \( a_i \) is at most \( c' \), therefore the total number of bits in \( p_i \) is at most \( c'-1 \) and the total number of bits in the sequence \( p_1, \ldots, p_j \) is at most \( (c-1)^2 \frac{c'+1}{c'-1} \). Consequently in \( M_d \) we may speak about the existence of a sequence \( p_1, \ldots, p_j \) in a firstorder way. Therefore, \( Pa = x \) will be equivalent to the following firstorder formula in \( M_d \): that there exists a sequence \( p_0, \ldots, p_{j-1} \), such that \( p_0 = 0 \), and for all \( i = 1, \ldots, j \), \( p_i = a_{i-1} p_{i-1} \) and \( p_j = x \). Q.E.D.

Now we show that condition (18) is satisfied by \( f = p \) and, for the proof of the Corollary, we show that it is satisfied by \( f = \bar{p} \). Since the proof for \( f = \bar{p} \) can be easily converted into a proof for \( f = p \) we describe here only the \( f = p \) case.

**Proposition 21** There exist strongly firstorder definable families \( f_q(d), d \in \omega, q = 0, 1, 2 \) such that for all sufficiently large \( d \) the following holds, where \( n = 2^d \):

(i) if \( a < 2^n \), then \( f_0(d)(a) \) is the sequence \( u = \langle u_0, \ldots, u_{j(a)-1} \rangle \), where \( u_i = a^{2^i} \), and \( j(a) \) is the smallest natural number with \( a^{2^{j(a)}} \geq 2^n \), and \( f_1(d)(a) = j(a) \).

(ii) if \( a < 2^n \) and \( b < j(a) \), then \( f_2((a, b)) = a^b \).

27
Proof. Statement (i) is an immediate consequence of Proposition 20. To prove statement (ii) assume that \( d \in \omega \) is sufficiently large \( a < 2^d \), \( b < j(a) \). We have \( b = \sum_{i=0}^{j(a)} \text{coeff}_i(b,2)2^i \). Proposition 8 implies that \( \alpha_i = \text{coeff}_i(b_2) \) is firstorder definable in \( M_d \). We may write \( a^b \) as the product \( \prod_{i=0}^{j(a)} a^i2^i \). Statement (i) and Proposition 20 together imply that \( a^b \) is firstorder definable in \( M_d \). Q.E.D. (Proposition 21)

The integer \( a^b \) can be written in the form of \( a^b = (a^j(a))^k a^l \), where \( t < j(a) \). Assume that \( a^b < 2^{d^c} \). Then \( a^j(a) > 2^n = n \) implies that \( k \leq c \) therefore according to Lemma 7 and Proposition 21 \( a^j(a) \) and \( a^l \) both can be defined in \( M_d \), and then again by Proposition (20) their product is also firstorder definable in \( M_d \). This completes the proof of condition (18) for \( f = \bar{p} \) and \( f = p \).

Now we prove condition (18) for \( f = \bar{z} \). Assume that \( a, b \in \mathbf{M}_{c+d} \) is given and we want to define \( [a/b] \) in \( M_d \) in a firstorder way. First we describe a way, using general mathematical language, to compute \( [a/b] \) and then we show that it can be translated into a firstorder formula of \( \mathcal{M} \) over \( M_d \).

(i) First we note that it is sufficient to find integers \( t, l \) such that \( \frac{1}{2} - t2^l < 2^{-2^{n-1}} \). The reason for this is that, \( a < 2^{d+c} = 2^{2^n} \) therefore in the possession of the integers \( t, l \) we can compute \( \alpha = at^2 \) and \( \lfloor \alpha - [a/b] \rfloor < \frac{1}{2} \) so we get \( [a/b] \) by rounding.

(ii) Let \( k \) be an integer so that \( 1 > 2^{-k}b > 1/2 \). If there exists no integer with this property then the problem is trivial, since we can get the binary bits of \( [a/b] \) form the bits of \( a \) simply by shift and the erasure of a block of consecutive bits. Let \( u = 2^{-k}b \). Since \( 1 > u > \frac{1}{2} \), we have \( 1 < \frac{1}{u} < 2 \). We may write \( \frac{1}{u} \) in the form of \( v2^{-(n+2)} + R \), where \( v \in [0,2^{n+2}] \) is an integer and \( 0 < R < 2^{-n-1} \). \( \nu \) will be determined by the first \( n + 1 \) bits of \( \frac{1}{u} \), and \( R \) is what remains from \( \frac{1}{u} \) after erasing these bits.) Let \( z = v2^{-(n+2)} \). The definition of \( v \) implies that \( 0 \leq z \leq 2 \).

(iii) We have \( zb = 1 + Rz = 1 + r \), where \( |r| < 2^{-n+1} \). We consider the series \( \frac{1}{zb} = \frac{1}{1 - (1 - zb)} = \frac{1}{1 - (-1)} = 1 - r + r^2 - r^3 + \ldots \). Let \( w \) be the sum of the first \( 42^c \) terms of this geometric series. Clearly \( w = \frac{1}{zb} + R_1 \), where \( |R_1| < 2^{-32n} \). Consequently \( \frac{1}{b} = \frac{1}{zb} = z(w - R_1) = zw + R_2 \), where \( |R_2| < 2^{-2^{n+1}} \).

Now we show that all of the quantities in this computation can be defined in a firstorder way in \( M_d \).

Stage (i). The definition of \( t \) and \( l \) will be described later. However if we have \( t \) and \( l \) then Proposition 19 implies that we may define the product \( at^2l \) in a firstorder way in \( M_d \). The rounding also can be done in a firstorder way.

Stage (ii). The integer \( v \) has only \( n + 2 \) bits. In \( M_d \) we can quantify \( n \) bits with a single existential quantifier, therefore \( v \) with the given property is firstorder definable in \( M_d \).

Stage (iii). Proposition 19 implies that the product \( zb \) can be defined in \( M_d \). Using Lemma 6 we get that \( r \) can be defined as well. Each needed terms of the geometric series can be defined in \( M_d \), we define the \( i \)th term as a product with \( i \) factors. Lemma 7 implies that such a product can be defined in \( M_d \) and by Lemma 6 the sum of the first \( 4d \) terms can be defined as well. Therefore we defined \( w \) and by Proposition 19 we can define \( zw \) as well. This completes the proof of the fact that condition (18) is satisfied by \( f = \bar{z} \), and also the proof of predictivity of \( \mathcal{M} \). Q.E.D. (Theorem 1)
4 A counterexample related to Theorem 2

In this section we give an example for a \( K \)-sequence \( K \) where the conclusion of Theorem 2 does not hold. (Naturally some of the assumptions of the theorem do not hold either.)

**Lemma 8** Assume that \( L \) is a firstorder language with equality, with no relation symbols other than equality, and with a finite number of constant and function symbols, among them the constant symbol \( 0 \). Then there exists an extension \( L' \) of \( L \) with a finite number of function symbols, and there exists a function which assigns to each term \( F(x,y) \) of \( L' \) a term \( G_F(x) \) of \( L' \) so that the following holds.

Assume that for all \( n \in \omega \), \( M_n \) is an interpretation of \( L \) with \( \text{universe}(M_n) = 2^n \) and with \( (0)_{M_n} = 0 \). Then for all \( n \in \omega \), there exists an interpretation \( M'_n \) of \( L' \) so that \( \text{universe}(M'_n) = \text{universe}(M_n) \), \( M'_n \) is an extension of \( M_n \) and the sequence \( M'_n, n \in \omega \) has the following property. For all terms \( F(x,y) \) of \( L' \) and for all sufficiently large \( n \in \omega \), we have

\[
M'_n \models \forall a, \left( G_F(a) = 0 \leftrightarrow \exists x, F(x,a) = 0 \right)
\]

Proof. First we describe the language \( L' \) and the interpretations of some of its function symbols. Then we will sketch the the main ideas of proof. Assume that \( f_0, \ldots, f_{k-1} \) are function symbols of a firstorder language \( L_1 \) each with arity \( r \). We will say that the sequence \( f = (f_0, \ldots, f_{k-1}) \) is a \( k \)-dimensional function symbol vector of \( L_1 \) with arity \( r \). If it does not cause any misunderstanding we will write \( M_n \) instead of \( \text{universe}(M_n) \).

The definition of \( L' \). We get \( L' \) by extending \( L \) with

(i) a unary function symbol \( a \),

(ii) a function symbol \( h \) with arity four, and

(iii) with a four dimensional function symbol vector \( g = (g_0, g_1, g_2, g_3) \) with arity six.

We will interpret \( a \) in the following way, for each \( n \), if \( u, v \in 2^n \) and \( u + 1 \equiv v \) (mod \( 2^n \)), then \( M_n \models a(u) = v \). That is \( (a)_{M_n} \) is the function adding 1 mod \( 2^n \). For each \( b \in \omega \), \( \tilde{b} \) will denote the term \( \tilde{a}(a_0) \) containing exactly \( b \) copies of \( a \). Clearly if \( 2^n > b \) then \( M_n \models a(\tilde{b}) = b \).

Let \( T_0(x,y), T_1(x,y), \ldots \) be an enumeration of all binary terms of \( L' \), each may contain only the free variables \( x, y \). We assume that if \( i < j \) then \( \text{length}(T_i) \leq \text{length}(T_j) \).

We fix a function \( \vartheta(n), n \in \omega \) so that \( \vartheta(n) \) tends to infinity very slowly, in the sense that in the proof we will require several times that \( n \) is sufficiently large with respect to \( \vartheta(n) \). These requirements will define the needed growth rate of \( \vartheta \).

Assume that \( F(x,y) = T_b(x,y) \) is a term of \( L' \). We define the term \( G_F(z) \) in the following way. First we define a sequence of four dimensional vector terms which may contain only the free variables \( x, y \) (a vector term of dimension \( d \) is a sequence consisting of \( d \) terms). The sequence \( s_0(x,y), s_1(a,b), \ldots, s_i(a,b), \ldots \) of four dimensional vector terms is defined by recursion on \( i \). \( s_0(x,y) = \langle x, y \rangle \). Assume that \( s_i(x,y) \) has been already defined. Then \( s_{i+1}(x,y) = g'(s_i(x,y), x, y) \). (This is well-defined since \( g \) has arity six and \( s_i(x,y) \) is a four dimensional vector.) We define the term \( G_F(z) \) by \( G_F(z) = h(s_{\vartheta(n)}(z, \tilde{b})) \).

Now we define \( M'_n \). We have already defined \( (a)_{M'_n} \). We define now \( g^{(n)} = (g)_{M'_n} \) the interpretation of \( g \) on the structure \( M'_n \). We define \( g^{(n)} \) in the following way. For each fixed \( a, b \in M_n \) we define the function \( g_{a,b}(x) = g^{(n)}(x,a,b), x \in M^4_n \). The function \( g_{a,b} \) mapping
For each fixed $i \in \omega$ if $n$ is sufficiently large, $a, b, u \in M_n$, $b \leq \vartheta(\vartheta(n))$ then the probability of $s_{\vartheta(n)}(a, b) \in V_i(a, u)$ is at most $c_2^2 \vartheta(n)|M_n|^{-4}$, where $c_2 > 1$ depends only on $\mathcal{L}$.
Since \( n \) is sufficiently large with respect to \( i \), \( \vartheta(n) \) is also sufficiently large with respect to \( i \). \( g(x,a,b) \) is a permutation of \( M_n^t \) with one cycle, therefore there exists an \( j = 1, \ldots, \vartheta(n) \) such that \( s_j(a,b) \notin V_j(a,u) \). Since the permutation is chosen with uniform distribution with the mentioned property, the probability that there exists a \( j' \in [j+1, \vartheta(n)] \), such that \( s_{j'}(a,b) \in V_i(a,u) \) is at most \( |V_i(a,u)|^2 \vartheta(n)|M_n|^{-4} \), and so \( |V_i(a,u)| \leq c_1 \) implies the conclusion of the proposition. Q.E.D. (Proposition 22)

Proposition 23 with a probability of at least \( 1 - 2^{-n} \) with respect to the randomization of the function \( g^{(n)} \) the following conditions are satisfied:

(22) for each fixed \( x \in M_n^4 \), there exists at most one pair \( a,b \in M_n \) such that \( b \leq \vartheta(n) \) and \( M_n' \models x = s_{\vartheta(n)}(a,b) \)

(23) for all \( x \in M_n^4 \), \( h^{(n)}(x) \neq 0 \) implies that \( x \notin \bigcup\{V_i(a,u)\}a,u \in M_n, i \in [0, \vartheta(n)] \).

Proof. First we show that condition (22) is satisfied. Assume that we randomize all of the values of \( g^{(n)} \) involved in the computation of all of the values \( s_i(a,b) \) with \( 0 \leq i \leq \vartheta(n) \), \( 0 \leq b \leq \vartheta(n) \), \( a \in M_n \). This is altogether no more then \( (\vartheta(n))^2|M_n| = (\vartheta(n))2^{|n|} \) values out of the total \( |M_n^4| = 2^{4n} \). Assume that we randomize these values of \( g^{(n)} \) sequentially, fixing first \( a,b \) and then we randomize the values of \( g^{(n)} \) which is needed to determine \( s_i(a,b) \) for \( i = 0,1, \ldots, \vartheta(b) \). At the time when we have to choose \( s_{\vartheta(b)}(a,b) \) and the corresponding value of \( g^{(n)} \) we have already chosen at most \( (\vartheta(n))2^{|n|} \) values of the cyclic permutation \( g_{a,b} \). Therefore the probability that we will choose a value which already occurred in the process as a value of \( g^{(n)} \) is at most \( (\vartheta(n))^2 - 2^3 \). Therefore the probability that this will happen for some \( a,b \) and \( i \) with the given restrictions is at most \( (\vartheta(n))^4 2^{-2n} \leq 2^{-2n} \).

Condition (23) Assume that an \( x \in M_n^4 \) is fixed with \( h^{(n)}(x) \neq 0 \). For each fixed \( a,u \in M_n \), \( i \in [0, \vartheta(n)] \) we give an upper bound on \( p_{a,u,i} \), the probability of the event \( x \in \bigcup\{V_i(a,u)\}a,u \in M_n, i \in [0, \vartheta(n)] \).

By the definition of \( h^{(n)} \), \( h^{(n)}(x) \neq 0 \) implies that \( x = s_{\vartheta(n)}(a,b) \) for suitably chosen \( a \) and \( b \). Therefore Proposition 22 implies that \( p_{a,u,i} \leq c_2 \vartheta(n)^4|M_n|^{-1} \). Adding the \( p_{a,u,i} \) for all possible values for \( a,u,i \) we get that the probability that (23) does not hold is at most \( \vartheta(n)^4|M_n|^{-2} \leq |M_n|^{-1} = 2^{-n} \). Q.E.D. (Proposition 23).

Proposition 24 For all terms \( F(x,y) \) of \( L' \), for all sufficiently large \( n \in \omega \), with a probability of at least \( 1 - 2^{-n} \) the following holds:

(24) for all \( a \in M_n \), \( M_n' \models \exists x, \Phi(x,a) \) iff \( M_n'' \models \exists x, \Phi(x,a) \)

Proof. Clearly it is sufficient to show that conditions (22) and (23) of Proposition 23 imply condition (24) of this proposition. Assume that \( u \in M_n \). Let \( W \) be the set of all elements \( w \) of \( M_n \) such that there is a subterm \( t \) of \( F \) with \( t(u,a) = w \). Since \( n \) is sufficiently large we may assume that \( \vartheta(\vartheta(n)) > 1\text{length}(F) \). Therefore condition (23) implies that \( h^{(n)}(w) = 0 \) for all \( w \in W \), and we have by definition \( (h)_{M_n^t}(w) = 0 \), for all \( w \in W \). Since for all other function symbols \( f \) of \( L' \), \( (f)_{M_n^t} = (f)_{M_n''} \), we can prove by induction of the depth of a subterm \( t \) of \( F \) that \( (t(u,a))_{M_n^t} = (t(u,a))_{M_n''} \), and therefore \( (F(u,a))_{M_n^t} = (F(u,a))_{M_n''} \). Since this is true for all
u ∈ M_n we get the equivalence of \( M'_n \models \exists x, \Phi(x, a) \) and \( M''_n \models \exists x, \Phi(x, a) \). Q.E.D.(Proposition 24)

We return now to the proof of Lemma 8. Let \( F(x, y) \) be a term of \( \mathcal{L}' \), and suppose that \( n \) is sufficiently large with respect to \text{length}(F). We show that with a probability of at least \( p_n = 2^{-n+1} \) we have that for all \( a \in M_n \),

\begin{equation}
M'_n \models G_F(a) = 0 \iff \exists x, F(x, a) = 0
\end{equation}

Since \( \sum_{n=0}^{\infty} p_n < \infty \) this will imply that with a probability 1 condition (25) holds for each sufficiently large \( n \), that is the conclusion of Lemma 8 holds.

Proposition 23 and Proposition 24 imply that it is sufficient to prove that if all the three conditions (22), (23), and are satisfied by the structure \( M'_n \) then condition (25) is also satisfied by \( M_n \). Assume now that the requirements of conditions (22), (23), and are met. Condition (22) and the definition of \( h^{(n)} \) implies that By definition by the definition of \( G_F \) we have \( M'_n \models G_F(a) = 1 - h(s_{\varphi(n)}(a, b)) \), where \( F(x, y) = T_b(x, y) \). Condition (22) and the definition of \( h^{(n)} \) implies that \( h(s_{\varphi(n)}(a, b)) = 1 \) iff \( M''_n \models \exists x, F(x, a) \). By condition (24) this is equivalent to \( M'_n \models \exists x, F(x, a) \) which completes the proof of condition (25).
