Abstract

We consider the point-to-point message passing model of communication in which there are k processors with individual private inputs, each n-bit long. Each processor is located at the node of an underlying undirected graph and has access to private random coins. An edge of the graph is a private channel of communication between its endpoints. The processors have to compute a given function of all their inputs by communicating along these channels. While this model has been widely used in distributed computing, strong lower bounds on the amount of communication needed to compute simple functions have just begun to appear.

In this work, we prove a tight lower bound of $\Omega(kn)$ on the communication needed for computing the Tribes function, when the underlying graph is a star of $k+1$ nodes that has k leaves with inputs and a center with no input. Lower bound on this topology easily implies comparable bounds for others. Our lower bounds are obtained by building upon the recent information theoretic techniques of Braverman et.al ([BEO$^+$13], FOCS'13) and combining it with the earlier work of Jayram, Kumar and Sivakumar ([JKS03], STOC'03). This approach yields information complexity bounds that is of independent interest.

1 Introduction

The classical model of 2-party communication was introduced in the seminal work of Yao[Yao79], motivated by problems of distributed computing. This model has proved to be of fundamental importance (see the book by Kushilevitz and Nisan [KN97]) and forms the core of the vibrant subject of communication complexity. It is fair to say that the wide applicability of this model to different areas of computer science cannot be over-emphasized.

However, a commonly encountered situation in distributed computing is one where there are multiple processors, each holding a private input, that are connected by an underlying communication graph. An edge of the graph corresponds to a private channel of communication between the endpoints. There are k processors located on distinct nodes of the graph that want to compute a function of their joint inputs. In such a networked scenario, a very natural question is to understand how much total communication is needed to get the function computed. The classical 2-party model is just a special case where the graph is an edge connecting two processors.

Among others, this model has also been called the Number-in-hand multiparty point-to-point message passing model of communication. Apart from distributed computing, this model is used in secure multiparty computation. The study of the communication cost in the model was most likely introduced by Dolev and Feder [DF92] and further worked on by Duris and Rolim [DR98]. These early works focused on deterministic communication. There has been renewed interest in the model because it arguably better captures many of today's networks that is studied in various distributed models: models for map-reduce [KSV10, GSZ11], massively parallel model for computing conjunctive queries [BKS13, KS11], distributed models of learning [BBFM12] and in core distributed computing [DKO12]. However, there were no known systematic techniques of proving lower bounds on the cost of randomized communication protocols that exploited the *non-broadcast* nature of the *private channels* of communication in the model. Recently, there has been a flurry of work developing new techniques for proving lower bounds on communication. Phillips, Verbin and Zhang [PVZ12] introduced the method of symmetrization to prove strong bounds for a variety of functions. Their technique was further developed in the works of Woodruff and Zhang [WZ12, WZ13, WZ14].

All these works considered the co-ordinator model, a special case, that was introduced in the early work of [DF92]. In the co-ordinator model, the underlying graph has the star topology with $k+1$ nodes. There are k leaves, each holding an n-bit input. Each of the k leaf-nodes is connected to the center of the star. The node at

ISSN 1433-8092

the center has no input and is called the co-ordinator. The following two simple observations about the model will be relevant for this work: every function can be trivially computed using $O(nk)$ bits of communication by having each of the k players send their inputs to the co-ordinator who then outputs the answer. It is also easily observed that the co-ordinator model can simulate a communication protocol on an arbitrary topology having k nodes with at most a $\log k$ factor blow-up in the total communication cost.

A key lesson learnt from our experience with the classical 2-party model is that an excellent indicator of our understanding of a model is our ability to prove lower bounds for the widely known Set-Disjointness problem in the model. Indeed, as surveyed in [CP10], several new and fundamental lower bound techniques have emerged from efforts to prove lower bounds for this function. Further, the lower bound for Set-Disjointness, is what drives many of the applications of communication complexity to other domains. While the symmetrization technique of Phillips et.al and its refinements by Woodruff and Zhang proved several lower bounds, no strong lower bounds for Set-Disjointness were known until recently in the k-processor co-ordinator model. In this setting, the relevant definition of Set-Disjointness is the natural generalization of its 2-party definition: view the n-bit inputs of the k processors as a $k \times n$ Boolean matrix where the ith row corresponds to the Processor i's input. The Set-Disjointness function outputs 1 iff there exists a column of this matrix that has no zeroes.

In an important development, Braverman et.al. [BEO$^+$13] proved a tight $\Omega(kn)$ lower bound for Set-Disjointness in the co-ordinator model. Their approach is to build up new information complexity tools for this model that is a significant generalization of the 2-party technique of Bar-Yossef et.al. [BJKS02]. In this work, we further develop this information complexity method for the co-ordinator model by considering another natural and important function, known as $\mathsf{Tribes}_{m,\ell}$. In this function, the n-bit input to each processor is grouped into m blocks, each of length ℓ. Thus, the overall $k \times n$ input matrix splits up into m sub-matrices $A_1, \ldots, A_m$, each of dimension $k \times \ell$. Tribes outputs 1 iff the Set-Disjointness function outputs 1 on each sub-matrix A_i. This obviously imparts a direct-sum flavor to the problem of determining the complexity of the Tribes function in the following sense: a naive protocol will solve Tribes by simultaneously running an optimal protocol for Set-Disjointness on each of the m instances $A_1, \ldots, A_m$. Is this strategy optimal?

This question was answered in the affirmative for the 2-party model by Jayram, Kumar and Sivakumar [JKS03] when they proved an $\Omega(n)$ lower bound on the randomized communication complexity of the Tribes function. Their work delicately extended the information theoretic tools of Bar-Yossef et.al [BJKS02]. Interestingly, it also exhibited the power of the information complexity approach. There was no other known technique to establish a tight lower bound on the Tribes function[1].

In this work, we show that the naive strategy for solving Tribes is optimal also in the co-ordinator model:

Theorem 1. *In the k-processor co-ordinator model, every bounded error randomized protocol solving the $\mathsf{Tribes}_{m,\ell}$ function, has communication cost $\Omega\big(m\ell k\big)$, for every $k \geq 2$.*

We prove this by extending and simplifying the information complexity approach of [BEO$^+$13] and the earlier work of [JKS03]. It is worth noting that our bounds in Theorem 1 hold for all values of k. In particular, this also yields a lower bound for Set-Disjointness for all values of k. The earlier bound of Braverman et.al. only worked if $k = \Omega(\log n)$.

2 Overview & comparison with previous work

We first provide a quick overview of our techniques and contributions. We follow this up with a more detailed description, elaborating on the main steps of the argument.

Brief Summary: Recall that the $\mathsf{Tribes}_{m,\ell}$ function can be written as an m-fold AND of Disj_ℓ instances. One possible way to show that $\mathsf{Tribes}_{m,\ell}$ is hard in message-passing model is to show that any protocol evaluating $\mathsf{Tribes}_{m,\ell}$ must evaluate all the the Disj_ℓ instances. This suffices to argue that $\mathsf{Tribes}_{m,\ell}$ is m times as hard as Disj_ℓ. By now it is well known that information complexity provides a convenient framework to realize such direct sum arguments. In order to do so, one needs to define a distribution on inputs that is entirely supported on the ones of the m Set-Disjointness instances of Tribes. This was the general strategy of Jayram et.al.[JKS03] in the 2-party context. However, the first problem one encounters is to define an appropriate hard distribution and a right notion of information cost such that Disjointness has high information cost of $\Omega(k\ell)$ under that distribution *in the co-ordinator model*. This turns out to be a delicate and involved step. Various natural information costs do not work as observed by Phillips et.al.[PVZ12]. Here, we are helped by the work of Braverman et.al.[BEO$^+$13]. They come up with an appropriate distribution τ and an information cost measure IC^0. However, we face two problems in using them. The first is that τ happens to be (almost) entirely supported on the zeroes of Set-Disjointness. Taking ideas from [JKS03], we modify τ to get a distribution μ supported exclusively on the ones of Set-Disjointness. Roughly speaking, to sample from μ, we first sample from τ and then pick a random

[1] This is not surprising. Two other successful techniques, the discrepancy and the corruption method, both yield lower bounds on the non-deterministic complexity. On the other hand, Tribes and its complement, on n-bit inputs, both have only $\sqrt{n}$ non-deterministic complexity.

column of the sampled input and force it to all ones. Intuitively, the idea is that the all ones column is being well hidden at a random spot. If τ was hard, μ should also remain hard. The second problem is to appropriately modify the information cost measure IC^0 to IC so that it yields high information complexity under μ. Here, we use an idea of [JKS03].

However, proving that IC is high for protocols when inputs are sampled according to μ raises new technical challenges. The first challenge is to prove a direct sum result on the information complexity of protocols as measured by IC. Implementing this step is a novelty of this work, where we show roughly that $\mathsf{IC}\big(\mathsf{Disj}_\ell\big)$ is at least $\Omega(\ell \cdot \mathsf{IC}\big(\mathsf{Disj}_2\big))$. For showing this, we introduce a new information measure, $\mathsf{PIC}(f)$ which is a lower bound on $\mathsf{IC}(f)$ and will be explained in relevat section. The final challenge is to prove that $\mathsf{IC}\big(\mathsf{Disj}_2\big)$ is $\Omega(k)$. We again do that by first simplifying some of the lemmas of [BEO$^+$13] and extending them using some ideas from the work of [JKS03].

More Detailed Account: Among the many possible ways to define information cost of a protocol, the definition we work with stems from the inherent structure of the communication model. As evident from the previous discussion, in the model of communication we are interested in, the co-ordinator can see the whole transcript of the protocol but cannot see the inputs. On the other hand, the processors can only see a local view of the transcript - the message that is passed to them and the message they send - along with their respective inputs. From the point of view of the co-ordinator, who has no input, the information revealed by the transcript about the input can be expressed by $\mathbb{I}[X : \Pi(X)]$. This is small for the protocol where the co-ordinator goes around probing each player on each coordinate to see whether any player has 0 in it and gives up once she finds such a player.(We call it Protocol A). It is not hard to see that the information cost can only be as high as $O(n \log k)$ for protocol A. A relevant information cost measure from the point of view of processor i is $\mathbb{I}[X^{-i} : \Pi^i(X) \mid X^i]$ which measures how much information processor i learns about other inputs from the transcript. It turns out that this information cost is also very small for the protocol where all the processors send their respective inputs to the co-ordinator (We call this protocol as protocol B). Here $\mathbb{I}[X^{-i} : \Pi^i(X) \mid X^i]$ is 0 for all i. What is worth noticing is that in both protocols, if we consider the sum of the two information costs, i.e., $\mathbb{I}[X : \Pi(X)] + \sum_i \mathbb{I}[X^{-i} : \Pi^i(X) \mid X^i]$, it is $\Omega(nk)$ which is the kind of bound we are aiming for.

This cost trade-off was first observed in [PVZ12] but they were unable to prove a lower bound for Disj_ℓ in this model of communication. Braverman et al [BEO$^+$13] solved this problem by coming up with the following notion of information complexity. Let $(\mathbf{X}, \mathbf{M}, \mathbf{Z})$ be distributed jointly according to some distribution τ. The information cost of a protocol Π with respect to τ is defined as,

$$\mathsf{IC}^0_\tau(\Pi) = \sum_{i \in [k]} \Big[\mathop{\mathbb{I}}_{\tau}[\mathbf{X}^i : \Pi^i(\mathbf{X}) \mid \mathbf{M}, \mathbf{Z}] + \mathop{\mathbb{I}}_{\tau}[\mathbf{M} : \Pi^i(\mathbf{X}) \mid \mathbf{X}^i, \mathbf{Z}] \Big] \tag{1}$$

Conditioning on the auxiliary random variables $\mathbf{M}$ and $\mathbf{Z}$ serves the following purpose: Even though the distribution τ is a non-product distribution, it can be thought of as a convex combination of product distributions, one for each specific values of $\mathbf{M}$ and $\mathbf{Z}$. It is well-known by now that such convex combination facilitates proving direct-sum like result.

The desired properties of the distribution τ are as follows. First, the distribution should have enough entropy to make it hard for the players to encode their inputs cheaply and send it across to the co-ordinator. Such an encoding is attempted in protocol B. Second, the distribution should be supported on inputs which have only a few 0's in each column of Disj_ℓ. This makes sure that the co-ordinator has to probe $\Omega(k)$ processors in each column before he finds a 0 in that column. This attempt of probing was undertaken by the co-ordinator in protocol A. The first property can be individually satisfied by setting each processor's input to be 0 or 1 with equal probability in each column. The second property can also be individually satisfied by taking a random processor for each column and giving it a 0 and giving 1 to rest of the processors as their inputs. Let $\mathbf{Z}_j$ denote the processor whose bit was fixed to 0 in column j. The hard distribution for Disj_ℓ is a convex combination of these two distributions. The way it is done is by setting a Bernoulli random variable $\mathbf{M}_j$ for each of the column j which acts as a switch, i.e., if $\mathbf{M}_j = 0$ the input to the column j is sampled from the first distribution, otherwise it is sampled from the second distribution. $\mathbf{M}_j$ takes value 0 with probability 2/3. We define $\mathbf{M} = \langle \mathbf{M}_1, \ldots, \mathbf{M}_\ell \rangle$ and $\mathbf{Z} = \langle \mathbf{Z}_1, \ldots, \mathbf{Z}_\ell \rangle$.

At this point it is interesting to go back to the definition of IC^0 and try to see the implication of each term in the definition. For the coordinator, $\sum_i \mathop{\mathbb{I}}_{\tau}[\mathbf{X}^i : \Pi^i(\mathbf{X}) \mid \mathbf{M}, \mathbf{Z}]$ represents the amount of information revealed about the inputs of the processors by the transcript. For convenience, we can assume that $\mathbf{M}$ is with co-ordinator. We can do this without loss of generality as the co-ordinator can sample $O(\log k)$ inputs from column j and conclude the value of $\mathbf{M}_j$ from it, for any j. This amount of communication is okay for us as we are trying to show a lower bound of $\Omega(nk)$. However note that we cannot assume that the processors have the knowledge of $\mathbf{M}$. Had that been the situation, the processors would have employed protocol A or protocol B in column j depending on the value of the $\mathbf{M}_j$. The value of $\mathbb{I}[\mathbf{X}^i : \Pi^i(\mathbf{X}) \mid \mathbf{M}, \mathbf{Z}]$, in this protocol, would have been small. So we need to make sure that we charge the processors for their effort to know the value of $\mathbf{M}$. This is taken care by the second term in the definition of IC^0 i.e., $\mathop{\mathbb{I}}_{\mu}[\mathbf{M} : \Pi^i(\mathbf{X}) \mid \mathbf{X}^i, \mathbf{Z}]$. Braverman et al [BEO$^+$13] used this

notion of information complexity to achieve the $\Omega(\ell k)$ lower bound for the information cost of Disj_ℓ with respect to the hard distribution.

As mentioned before, we, however, need the hard distribution ζ for $\mathsf{Tribes}_{m,\ell}$ to be entirely supported on 1s of Disj_ℓ. But the distribution τ described above is supported on 0s of Disj_ℓ. Here we borrow ideas from [JKS03] and design a distribution μ by selecting a random column for the Disj_ℓ instances and planting an all 1 input in it. We denote the random co-ordinate by $\mathbf{W}$. It is easy to verify that μ is a distribution supported in 1s of Disj_ℓ. We set the hard distribution for $\mathsf{Tribes}_{m,\ell}$ to be an m-fold product distribution $\zeta = \mu^m$ denoted by the random variables $\langle \bar{\mathbf{X}}, \bar{\mathbf{M}}, \bar{\mathbf{Z}}, \bar{\mathbf{W}} \rangle$. It is to be noted that a correct protocol should work well for all inputs, not necessarily for the inputs coming from the distribution ζ. This property will be crucially used in later part of the proof. The modification of the input distribution from τ to μ and subsequently to ζ calls for changing the definition of the information complexity to suit our purpose. We define information complexity as follows which we will use in this paper.

Definition 2. *Let $(\bar{\mathbf{X}}, \bar{\mathbf{M}}, \bar{\mathbf{Z}}, \bar{\mathbf{W}})$ be distributed jointly according to ζ. The information cost of a protocol Π with k processors in NIH point-to-point coordinator model with respect to ζ is defined as,*

$$\mathsf{IC}_\zeta(\Pi) = \sum_{i \in [k]} \left[\mathop{\mathbb{I}}_{\zeta}[\bar{\mathbf{X}}^i : \Pi^i(\bar{\mathbf{X}}) \mid \bar{\mathbf{M}}, \bar{\mathbf{Z}}, \bar{\mathbf{W}}] + \mathop{\mathbb{I}}_{\zeta}[\bar{\mathbf{M}} : \Pi^i(\bar{\mathbf{X}}) \mid \bar{\mathbf{X}}^i, \bar{\mathbf{Z}}, \bar{\mathbf{W}}] \right]. \tag{2}$$

For a function $f : \mathbf{X} \to \mathcal{R}$, the information complexity of the function is defined as,

$$\mathsf{IC}_{\zeta,\delta}(f) = \inf_{\Pi} \mathsf{IC}_\mu(\Pi), \tag{3}$$

where the infimum is taken over all δ-error protocol Π for f.

By doing this, we are able to bound the information complexity of $\mathsf{Tribes}_{m,\ell}$ as m-times that of Disj_ℓ. Although non-trivial, this step can be accomplished by exploiting the proof techniques used in [BEO$^+$13]. The next step is to bound the information complexity of Disj_ℓ, which turns out to be difficult for two reasons. First, the distribution μ is no more a 0 distribution for Disj_ℓ. We get around this by defining a new information complexity measure, - which we call as partial information complexity - to show that the partial information complexity of Disj_ℓ on distribution μ is at least $(\ell - 1)$-times that of Disj_2. This is one of the main technical contributions of our paper. See Section 4.1 for details. The second hurdle we face is bounding the information complexity of Disj_2. Here we combine ideas from [JKS03, BEO$^+$13] to conclude that the partial information complexity of Disj_2 is $\Omega(k)$. This is the second main technical contribution of this paper, which is explained in Section 4.2. Finally we give a simple argument in Section 5 to show that $\mathsf{IC}_\zeta(\Pi)$ lower bounds the communication cost of Π where Π is any correct protocol for $\mathsf{Tribes}_{m,\ell}$.

3 Preliminaries

Communication complexity. In this work, we are mainly interested in multiparty communication *number-in-hand* model. In this model of computation, the input is distributed between k players $P_1, \cdots, P_k$ who jointly wish to compute a function f on the combined input by communication with each other. It can be assumed that the players have unlimited computational power. Several variants of this model have been studied extensively, such as, message passing model, where each pair of players have a dedicated communication channel and hence the players can send messages to specific players. This is contrasted in the second variant where the players can only broadcast their communication. The latter model in known as shared blackboard model. In this work, we consider the message passing model.

As mentioned before, the model which is easier to work with is the coordinator model where, in addition to k players who hold the input, a coordinator is introduced who does not have any input but all the communication is channelled via her, i.e., the players can only communicate with the coordinator though the coordinator is allowed to communication with everybody. It is easy to observe that this coordinator model can simulate the message passing model with only a $\log k$ overhead in the total communication cost.

We work with randomized protocol where the players have access to private coins. (Though it might seem like that the public coin protocol can yield better upper bound, it can be noted that all the proofs can be modified to give the same result for public coin model.) The standard notion of private coin randomized communication complexity is adopted here, where we look at the worst-case communication of the protocol when the protocol is allowed to make only δ error (bounded away from $1/2$) on each input. Here the probability is taken over the private coin tosses of the players. For more details, readers are referred to [KN97].

Information theory. We will quickly go through the information theoretic definitions and facts we need. For a random variable X taking value in the sample space Ω according to the distribution $p(\dot{})$, the entropy of X,

denoted as $\mathcal{H}(X)$, is defined as follows.

$$\mathcal{H}(X) = \sum_{x \in \Omega} \Pr[X = x] \log \frac{1}{\Pr[X = x]} = \mathbf{E}_x \left[\log \frac{1}{p(x)} \right]. \tag{4}$$

For two random variables X and Y, the conditional entropy of X given Y is defined as follows.

$$\mathcal{H}(X|Y) = \mathbf{E}_{x,y} \left[\log \frac{1}{p(x|y)} \right]. \tag{5}$$

Informally, the entropy of a random variable measures the uncertainty associated with it. Conditioning on another random variable, i.e., knowing the value that another random variable takes can only decrease the uncertainty of the former one. This notion is captured in the following fact that $\mathcal{H}(X|Y) \leq \mathcal{H}(X)$ where the equality is achieved when X is independent of Y. Given two random variables X and Y with joint distribution $p(x, y)$ we can talk about how much information one random variable reveals about the other random variable. The mutual information, as it is called, between X and Y is defined as follows.

$$\mathbb{I}[X : Y] = \mathcal{H}(X) - \mathcal{H}(X|Y). \tag{6}$$

It is to be noted that the mutual information is a symmetric quantity, though it might not be obvious from the definition itself. From the previous discussion, it is easy to see that the mutual information is a non-negative quantity. As before, we can also define conditional mutual information as below.

$$\mathbb{I}[X : Y|Z] = \mathcal{H}(X|Z) - \mathcal{H}(X|Y, Z). \tag{7}$$

The following chain rule of mutual information will be crucially used in our proof.

$$\mathbb{I}[X_1, \ldots, X_n : Y] = \sum_{i \in [n]} \mathbb{I}[X_i : Y|X_{i-1}, \ldots, X_1]. \tag{8}$$

It is to be noted that the chain rule of mutual information will also work when conditioned on random variable Z.

Remark 1. *Consider a permutation $\sigma : [n] \to [n]$. The following observation will be useful in our proof.*

$$\mathbb{I}[X_1, \ldots, X_n : Y] = \sum_{i \in [n]} \mathbb{I}[X_{\sigma(i)} : Y|X_{\sigma(i-1)}, \ldots, X_{\sigma(1)}]. \tag{9}$$

We will use the following lemmas regarding mutual information.

Lemma 3. *Consider random variables A, B, C and D. If A is independent of B given D then,*

$$\mathbb{I}[A : B, C \mid D] = \mathbb{I}[A : C \mid B, D], \tag{10}$$

and

$$\mathbb{I}[A : C \mid B, D] \geq \mathbb{I}[A : C \mid D]. \tag{11}$$

Proof. By chain rule of mutual information,

$$\begin{aligned} \mathbb{I}[A : B, C \mid D] &= \mathbb{I}[A : B \mid D] + \mathbb{I}[A : C \mid B, D] \\ &= \mathbb{I}[A : C \mid B, D] \qquad [\text{As } A \perp B|D \Rightarrow \mathbb{I}[A : B \mid D] = 0]. \end{aligned}$$

For the second expression, we know $\mathbb{I}[A : B|D] = 0$ which means $\mathcal{H}(A|D) = \mathcal{H}(A|B, D)$. Hence,

$$\begin{aligned} \mathbb{I}[A : C \mid B, D] &= \mathcal{H}(A|B, D) - \mathcal{H}(A|B, C, D) \\ &= \mathcal{H}(A|D) - \mathcal{H}(A|B, C, D) \\ &\geq \mathcal{H}(A|D) - \mathcal{H}(A|C, D) \\ &= \mathbb{I}[A : C \mid D]. \end{aligned}$$

□

4 Lower bound for $\mathsf{Tribes}_{m,\ell}$ in message-passing model

Here, in the first subsection, we will show two direct-sum results. In the first step we bound the information complexity of $\mathsf{Tribes}_{m,\ell}$ in terms of that of Disj_ℓ. It is to be noted that the proof technique of [BJKS02] falls short of proving any lower bound on the information complexity measure we have defined - mainly because of the fact the information complexity measure consists of sum two different mutual information terms for each processor, and it is not clear that one can come up with lower bounds for both the terms simultaneously. This problem has already been attended to in [BEO$^+$13] and the proof we present here resembles the proof technique used by them. For completeness we include the proof in this paper. In the second step, we will bound the information complexity of Disj_ℓ in terms of Disj_2. This step is more difficult and a straight-forward application of the direct-sum argument of [BEO$^+$13] will not work. First we use ideas from [JKS03] to define partial information complexity measure which is more convenient to work with. Then we come up with a novel direct-sum argument for partial information complexity measure.

In Section 4.2, we show that the information complexity of Disj_2 is $\Omega(k)$. We manage to show this by combining ideas from [BEO$^+$13, JKS03].

4.1 Direct sum

In this section we prove that the information cost of computing $\mathsf{Tribes}_{m,\ell}$ is m times the information cost of computing Disj_ℓ. The proof is almost the same proof as in [BEO$^+$13] where the authors have used a direct sum theorem to show that the information cost of computing Disj_ℓ is ℓ times the information cost of computing k-bit AND_k. Before going into details we need the following definitions

Consider $f : \mathcal{D}^m \to \mathcal{R}$ can be written as $f(X) = g(h(X_1), \ldots, h(X_m))$ where $X = \langle X_1, \ldots, X_m \rangle$, $X_i \in \mathcal{D}$ and $h : \mathcal{D} \to \mathcal{R}$. In other words, f is g-decomposable with primitive h.

Definition 4 (Collapsing distribution)**.** *We call $X \in \mathcal{D}^m$ be a collapsing input for f if for any $i \in [m]$ and $y \in \mathcal{D}$, we have $f(X(i, y)) = h(y)$. Any distribution ζ supported entirely on collapsing inputs on f is called a collapsing distribution of f.*

Definition 5 (Projection)**.** *Given a distribution ν specified by random variable $(D_1, \ldots, D_k)$ and a subset S of $[k]$, we call the projection of ν on $(D_i)_{i\in S}$, denoted as $\nu \downarrow_{(D_i)_{i\in S}}$, the marginal distribution of $(D_i)_{i\in S}$ induced by ν.*

The proof is by reduction: we will show that given a protocol Π for $\mathsf{Tribes}_{m,\ell}$ and a collapsing distribution $\mu = \zeta_l^m$, we can construct a protocol Π' for Disj_ℓ such that it computes Disj_ℓ with the same error probability as that of Π and the information complexity of Π is m times that of Disj_ℓ.

Theorem 6. *Let $\mu = \zeta_\ell^m$ be a collapsing distribution for $\mathsf{Tribes}_{m,\ell}$ partitioned by $\mathbf{M}, \mathbf{Z}$ and $\mathbf{W}$ as described before. Then*

$$\mathsf{IC}_\mu(\mathsf{Tribes}_{m,\ell}) \geq m.\mathsf{IC}_{\zeta_\ell}(\mathsf{Disj}_\ell). \tag{12}$$

As mentioned before, the proof of Theorem 6 works out nicely by adapting the proof techniques of [BEO$^+$13] and is given below. We will describe how to construct protocol Π' for Disj_ℓ given protocol Π for $\mathsf{Tribes}_{m,\ell}$. On an input u for Disj_ℓ, the processors and the coordinator sample a random $k \times m\ell$ matrix $\bar{\mathbf{X}}$ in the following way.

1. The coordinator samples $\mathbf{J}$ uniformly at random from $[m]$. This is the place where the processors embed the input u.
2. The coordinator samples $\bar{\mathbf{Z}}_{-\mathbf{J}} \in [k]^{\ell(m-1)}$ and sends it to all the processors.
3. The coordinator samples $\bar{\mathbf{W}}_{-\mathbf{J}} \in [\ell]^{m-1}$ and sends it to all the processors.
4. The coordinator samples $\mathbf{M}_t \in \{0, 1\}^\ell, \mathbf{M}_t \sim \mathsf{Bin}(1/3)$ for all t less that $\mathbf{J}$ and sends it to all the processors. The processors use their private randomness to sample the inputs for those Disj_ℓ instances in the following way: For the ith Disj_ℓ instance, the processors sample $\mathbf{X}$ by sampling each of the columns independently - For column j the input of the $\mathbf{Z}_j$th processor is fixed to 0 and the other processors get 1 if $\mathbf{M}_j = 1$, otherwise, they get 0 or 1 uniformly at random
5. For the rest of Disj_ℓ instances, the coordinator herself samples the inputs in the same way and sends the requisite inputs to respective processors.

Observation 7. *Consider the tuple $(\mathbf{U}, \mathbf{N}, \mathbf{V}, \mathbf{S})$ distributed according to ζ_l. If $\mathbf{U}$ is given as input to protocol Π', then $(\bar{\mathbf{X}}, \bar{\mathbf{M}}, \bar{\mathbf{Z}}, \bar{\mathbf{W}})$ is distributed according to μ.*

As μ is a collapsing distribution for $\mathsf{Tribes}_{m,\ell}$, it is easy to see that the protocol Π' computes Disj_ℓ. We need to show the connection between information cost of this protocol and the information cost of $\mathsf{Tribes}_{m,\ell}$ which is shown next.

We will prove the following lemma.

Lemma 8. *[BEO+13]*

$$\mathop{\mathbb{I}}_{(\mathbf{U},\mathbf{N},\bar{\mathbf{V}},\mathbf{S})\sim\zeta_\ell}[\mathbf{U}^i : \Pi'^i(\mathbf{U}) \mid \mathbf{N},\mathbf{V},\mathbf{S}] \leq \frac{1}{m}\mathop{\mathbb{I}}_{(\bar{\mathbf{X}},\bar{\mathbf{M}},\bar{\mathbf{W}},\bar{\mathbf{Z}})\sim\mu}[\bar{\mathbf{X}}^i : \Pi^i(\bar{\mathbf{X}}) \mid \bar{\mathbf{M}},\bar{\mathbf{W}},\bar{\mathbf{Z}}], \tag{13}$$

and

$$\mathop{\mathbb{I}}_{(\mathbf{U},\mathbf{N},\bar{\mathbf{V}},\mathbf{S})\sim\zeta_\ell}[\mathbf{N} : \Pi'^i(\mathbf{U}) \mid \mathbf{U}^i,\mathbf{V},\mathbf{S}] \leq \frac{1}{m}\mathop{\mathbb{I}}_{(\bar{\mathbf{X}},\bar{\mathbf{M}},\bar{\mathbf{W}},\bar{\mathbf{Z}})\sim\mu}[\bar{\mathbf{M}} : \Pi^i(\bar{\mathbf{X}}) \mid \bar{\mathbf{X}}^i,\bar{\mathbf{W}},\bar{\mathbf{Z}}]. \tag{14}$$

Lemma 8 implies Theorem 6.

Proof of Lemma 8. The proof is exactly same as the proof of Lemma 4.1 of [BEO+13].

We will prove Equation (14) first. Equation (13) can be proved similarly. Let's look at the view of processor i on the transcript Π', which we are calling as Π'^i. We have

$$\Pi'^i(\mathbf{U}) = \langle \mathbf{J}, \bar{\mathbf{Z}}_{-\mathbf{J}}, \bar{\mathbf{M}}_{[1,\mathbf{J}-1]}, \bar{\mathbf{X}}^i_{[\mathbf{J}+1,m]}, \bar{\mathbf{W}}_{-\mathbf{J}}, \Pi(\bar{\mathbf{X}}(\mathbf{J},\mathbf{U}))\rangle.$$

As $\langle \mathbf{J}, \bar{\mathbf{Z}}_{-\mathbf{J}}, \bar{\mathbf{M}}_{[1,\mathbf{J}-1]}, \bar{\mathbf{X}}^i_{[\mathbf{J}+1,m]}, \bar{\mathbf{W}}_{-\mathbf{J}}\rangle$ is independent of $\mathbf{N}$, we can write what follows.

$$\begin{aligned}
& \mathbb{I}_{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_\ell}[\mathbf{N} : \Pi'^i(\mathbf{U}) \mid \mathbf{U}^i,\mathbf{V},\mathbf{S}] \\
= & \mathop{\mathbb{I}}_{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_\ell \\ (\bar{\mathbf{Z}}_{-\mathbf{J}},\bar{\mathbf{M}}_{-\mathbf{J}},\bar{\mathbf{X}}_{-\mathbf{J}},\mathbf{W}_{-\mathbf{J}})\sim\zeta_\ell^{m-1}}} [\mathbf{N} : \langle \mathbf{J}, \bar{\mathbf{Z}}_{-\mathbf{J}}, \bar{\mathbf{M}}_{[1,\mathbf{J}-1]}, \bar{\mathbf{X}}^i_{[\mathbf{J}+1,m]}, \bar{\mathbf{W}}_{-\mathbf{J}}, \Pi(\bar{\mathbf{X}}(\mathbf{J},\mathbf{U}))\rangle \mid \mathbf{U}^i,\mathbf{V},\mathbf{S}] \\
= & \mathop{\mathbb{I}}_{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_\ell \\ (\bar{\mathbf{Z}}_{-\mathbf{J}},\bar{\mathbf{M}}_{-\mathbf{J}},\bar{\mathbf{X}}_{-\mathbf{J}},\mathbf{W}_{-\mathbf{J}})\sim\zeta_\ell^{m-1}}} [\mathbf{N} : \Pi(\bar{\mathbf{X}}(\mathbf{J},\mathbf{U})) \mid \mathbf{J}, \bar{\mathbf{Z}}_{-\mathbf{J}}, \bar{\mathbf{M}}_{[1,\mathbf{J}-1]}, \bar{\mathbf{X}}^i_{[\mathbf{J}+1,m]}, \bar{\mathbf{W}}_{-\mathbf{J}}, \mathbf{U}^i,\mathbf{V},\mathbf{S}] \\
= & \mathop{\mathbb{I}}_{(\bar{\mathbf{X}},\bar{\mathbf{M}},\bar{\mathbf{W}},\bar{\mathbf{Z}})\sim\mu}[\bar{\mathbf{M}}_{\mathbf{J}} : \Pi^i(\bar{\mathbf{X}}) \mid \mathbf{J}, \bar{\mathbf{M}}_{[1,\mathbf{J}-1]}, \bar{\mathbf{X}}^i_{[\mathbf{J},m]}, \bar{\mathbf{Z}}, \bar{\mathbf{W}}] \\
\leq & \mathop{\mathbb{I}}_{(\bar{\mathbf{X}},\bar{\mathbf{M}},\bar{\mathbf{W}},\bar{\mathbf{Z}})\sim\mu}[\bar{\mathbf{M}}_{\mathbf{J}} : \Pi^i(\bar{\mathbf{X}}) \mid \mathbf{J}, \bar{\mathbf{M}}_{[1,\mathbf{J}-1]}, \bar{\mathbf{X}}^i, \bar{\mathbf{Z}}, \bar{\mathbf{W}}] \\
= & \frac{1}{m}\sum_{j=1}^{m}\mathop{\mathbb{I}}_{(\bar{\mathbf{X}},\bar{\mathbf{M}},\bar{\mathbf{W}},\bar{\mathbf{Z}})\sim\mu}[\bar{\mathbf{M}}_j : \Pi^i(\bar{\mathbf{X}}) \mid \bar{\mathbf{M}}_{[1,j-1]}, \bar{\mathbf{X}}^i, \bar{\mathbf{Z}}, \bar{\mathbf{W}}] \\
= & \frac{1}{m}\mathop{\mathbb{I}}_{(\bar{\mathbf{X}},\bar{\mathbf{M}},\bar{\mathbf{W}},\bar{\mathbf{Z}})\sim\mu}[\bar{\mathbf{M}} : \Pi^i(\bar{\mathbf{X}}) \mid \bar{\mathbf{X}}^i, \bar{\mathbf{Z}}, \bar{\mathbf{W}}].
\end{aligned}$$

Equation (13) can be proved in the same way. □

Now our goal is to connect the information cost of Disj_ℓ under ζ_ℓ to information cost of AND_k. So a natural attempt is to prove a theorem like Theorem 6 for reduction from Disj_ℓ to AND_k. Unfortunately this is not possible. Recall that $\mathsf{Disj}_\ell(X) = \bigvee_{i=1}^{\ell}\bigwedge_{j=1}^{k} X_i^j$. Hence for a collapsing distribution each of the AND_ks should evaluate to 0, which is not the case for the distribution ζ_ℓ.

Inspired by [JKS03], we define the following measure of information cost, namely, partial information cost. Let Π be a protocol for Disj_ℓ. The partial information cost of Π is defined as,

$$\mathsf{PIC}(\Pi) = \sum_{i=1}^{k}\left(\mathbb{I}\left[\mathbf{M}_{-\mathbf{W}} : \Pi^i(\mathbf{X}) \mid \mathbf{X}^i,\mathbf{Z},\mathbf{W}\right] + \mathbb{I}\left[\mathbf{X}^i_{-\mathbf{W}} : \Pi^i(\mathbf{X}) \mid \mathbf{M},\mathbf{Z},\mathbf{W}\right]\right). \tag{15}$$

The random variable $\mathbf{M}_{-\mathbf{W}}$ denotes $\mathbf{M}$ with its $\mathbf{W}$-th coordinate removed. Similarly, $\mathbf{X}^i_{-\mathbf{W}}$ denotes $\mathbf{X}^i$ with its $\mathbf{W}$-th coordinate removed. The partial information complexity of Disj_ℓ is the partial information cost of the best protocol computing Disj_ℓ. It is easy to see that the partial information complexity of any function f lower bounds the information complexity of f.

We prove the following theorem.

Theorem 9. *Let ζ_ℓ be the distribution over the inputs of Disj_ℓ partitioned by $\mathbf{M},\mathbf{Z},\mathbf{W}$ as described before. Then*

$$\mathsf{PIC}_{\zeta_\ell}(\mathsf{Disj}_\ell) \geq (\ell-1).\mathsf{PIC}_{\zeta_2}(\mathsf{Disj}_2). \tag{16}$$

Here we will show the following reduction analogous to our previous reduction from $\mathsf{Tribes}_{m,\ell}$ to Disj_ℓ. Given a protocol Π' for Disj_ℓ and distribution ζ_ℓ (as described in Section 2, we will come up with a protocol Π'' for Disj_2 such that the partial information cost of Π'' w.r.t. ζ_ℓ is $1/(\ell-1)$ times the partial information cost of Π' w.r.t ζ_2.

Let us describe the construction of the protocol Π''. On an input $u = \langle u_1, u_2\rangle$ for Disj_2, the processors and the coordinator sample a $k \times \ell$ random matrix $\mathbf{X}(u)$ in the following way.

1. The coordinator samples $\mathbf{P}$ and $\mathbf{Q}$ uniformly at random from $[\ell]$ such that $\mathbf{P} < \mathbf{Q}$.
2. The coordinator samples $\mathbf{Z}_{-\{\mathbf{P},\mathbf{Q}\}} = (\mathbf{Z}_i)_{i\in[\ell]\setminus\mathbf{P},\mathbf{Q}}$, where each $\mathbf{Z}_i \underset{R}{\in} [k]$, and sends it to all the processors.
3. The coordinator samples a number $\mathbf{R}$ uniformly at random from $\{0, ..., \ell-2\}$ and then samples a subset $\mathbf{T} \subseteq [\ell]\setminus\{\mathbf{P},\mathbf{Q}\}$ uniformly at random from all sets of size $\mathbf{R}$ that do not contain $\mathbf{P}, \mathbf{Q}$. Then the coordinator samples $\mathbf{M}_t \sim \mathsf{Bin}(1/3)$ for all $t \in \mathbf{T}$ and sends them to all the processors. The processors use their private randomness to sample $\mathbf{X}_t$ for each column t in $\mathbf{T}$ in the following way: The input of the $\mathbf{Z}_t$-th processor is fixed to 0 in $\mathbf{X}_t$ and the other processors get 1 if $\mathbf{M}_t = 1$, otherwise, if $\mathbf{M}_t = 0$, they get 0 or 1 uniformly at random. We will call this input sampling procedure as $\mathsf{IpSample}$.
4. For the rest of the columns, the coordinator samples the inputs according to $\mathsf{IpSample}$ and sends the requisite inputs to the respective processors.
5. The processors form the input $\mathbf{X} \equiv \mathbf{X}(u, \mathbf{P}, \mathbf{Q})$ (i.e., $\mathbf{X}_\mathbf{P} = u_1$ and $\mathbf{X}_\mathbf{Q} = u_2$) and run the protocol Π' for Disj_ℓ with $\mathbf{X}$ as input.

Observation 10. *Consider the tuple* $(\mathbf{U}, \mathbf{N}, \mathbf{V}, \mathbf{S})$ *distributed according to* ζ_2. *If* $\mathbf{U}$ *is given as input to protocol* Π'', *then* $(\mathbf{X}, \mathbf{M}, \mathbf{Z}, \mathbf{W})$ *is distributed according to* ζ_ℓ, *where* $\mathbf{W}$ *is the unique all 1's coordinate in* $\mathbf{X}$. *Here* $\mathbf{W} = \mathbf{P}$ *if* $\mathbf{V} = 1$ *and* $\mathbf{W} = \mathbf{Q}$ *if* $\mathbf{V} = 2$.

Next we prove the following lemma connecting the information cost of Π' for Disj_ℓ and that of Π'' for Disj_2. This lemma implies the Theorem 9.

Lemma 11.

$$\underset{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2}{\mathbb{I}}[\mathbf{U}^i_{-\mathbf{V}}, \Pi''^i(\mathbf{U}) \mid \mathbf{N}, \mathbf{V}, \mathbf{S}] \le \frac{1}{\ell-1} \underset{(\mathbf{X},\mathbf{M},\mathbf{W},\mathbf{Z})\sim\zeta_\ell}{\mathbb{I}}[\mathbf{X}^i_{-\mathbf{W}}, \Pi'^i(\mathbf{X}) \mid \mathbf{M}, \mathbf{W}, \mathbf{Z}], \tag{17}$$

and

$$\underset{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2}{\mathbb{I}}[\mathbf{N}_{-\mathbf{V}}, \Pi''^i(\mathbf{U}) \mid \mathbf{U}^i, \mathbf{V}, \mathbf{S}] \le \frac{1}{\ell-1} \underset{(\mathbf{X},\mathbf{M},\mathbf{W},\mathbf{Z})\sim\zeta_\ell}{\mathbb{I}}[\mathbf{M}_{-\mathbf{W}}, \Pi'^i(\mathbf{X}) \mid \mathbf{X}^i, \mathbf{W}, \mathbf{Z}]. \tag{18}$$

Proof. We consider the LHS of Equation (18). The view of processor i of the transcript of protocol Π'', denoted as $\Pi''^i(\mathbf{U})$, is given as follows.

$$\Pi''^i(\mathbf{U}) = \langle \mathbf{P}, \mathbf{Q}, \mathbf{Z}_{-\mathbf{P},\mathbf{Q}}, \mathbf{R}, \mathbf{T}, \mathbf{M}_\mathbf{T}, \mathbf{X}^i_{\mathbf{T}\setminus\{\mathbf{P},\mathbf{Q}\}}, \Pi'(\mathbf{X}(\mathbf{P}, \mathbf{Q}, \mathbf{U}))\rangle. \tag{19}$$

So the LHS of Equation (18) can be written as

$$\begin{aligned}
&\underset{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2}{\mathbb{I}}[\mathbf{N}_{-\mathbf{V}} : \Pi''^i(\mathbf{U}) \mid \mathbf{U}^i, \mathbf{V}, \mathbf{S}] \\
&= \underset{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}}{\mathbb{I}}[\mathbf{N}_{-\mathbf{V}} : \mathbf{P}, \mathbf{Q}, \mathbf{Z}_{-\mathbf{P},\mathbf{Q}}, \mathbf{T}, \mathbf{M}_\mathbf{T}, \mathbf{R}, \mathbf{X}^i_{\mathbf{T}\setminus\{\mathbf{P},\mathbf{Q}\}}, \Pi'^i(\mathbf{X}(\mathbf{P}, \mathbf{Q}, \mathbf{U}))|\mathbf{U}^i, \mathbf{V}, \mathbf{S}] \\
&= \underset{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}}{\mathbb{I}}[\mathbf{N}_{-\mathbf{V}} : \Pi'^i(\mathbf{X}(\mathbf{P}, \mathbf{Q}, \mathbf{U}))|\mathbf{P}, \mathbf{Q}, \mathbf{Z}_{-\mathbf{P},\mathbf{Q}}, \mathbf{T}, \mathbf{M}_\mathbf{T}, \mathbf{R}, \mathbf{X}^i_{\mathbf{T}\setminus\{\mathbf{P},\mathbf{Q}\}}, \mathbf{U}^i, \mathbf{V}, \mathbf{S}] \quad \text{[Lemma 3 eqn. (10)]} \\
&= \underset{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}}{\mathbb{I}}[\mathbf{N}_{-\mathbf{V}} : \Pi'^i(\mathbf{X}) \mid \mathbf{P}, \mathbf{Q}, \mathbf{R}, \mathbf{T}, \mathbf{M}_\mathbf{T}, \mathbf{Z}, \mathbf{V}, \mathbf{X}^i_{\mathbf{T}}] \quad \text{[Combining } (\mathbf{U}^i, \mathbf{X}^i_{\mathbf{T}\setminus\{\mathbf{P},\mathbf{Q}\}}) \text{ and } (\mathbf{Z}_{-\mathbf{P},\mathbf{Q}}, \mathbf{S})] \\
&\le \underset{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}}{\mathbb{I}}[\mathbf{N}_{-\mathbf{V}} : \Pi'^i(\mathbf{X}) \mid \mathbf{P}, \mathbf{Q}, \mathbf{R}, \mathbf{T}, \mathbf{M}_\mathbf{T}, \mathbf{Z}, \mathbf{V}, \mathbf{X}^i] \quad \text{[Lemma 3 eqn. (11), } \mathbf{X}^i_\mathbf{S} \text{ ind. of } \mathbf{N}_{-\mathbf{V}}]
\end{aligned}$$

[V takes value in 1 and 2 uniformly at random. Hence we can write it as follows.]

$$\begin{aligned}
&= \frac{1}{2} \underset{(\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}{\mathbb{I}}[\mathbf{M}_\mathbf{P} : \Pi'^i(\mathbf{X}) \mid \mathbf{P}, \mathbf{Q}, \mathbf{R}, \mathbf{T}, \mathbf{M}_\mathbf{T}, \mathbf{Z}, \mathbf{V} = 2, \mathbf{X}^i] \\
&\quad + \frac{1}{2} \underset{(\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}{\mathbb{I}}[\mathbf{M}_\mathbf{Q} : \Pi'^i(\mathbf{X}) \mid \mathbf{P}, \mathbf{Q}, \mathbf{R}, \mathbf{T}, \mathbf{M}_\mathbf{T}, \mathbf{Z}, \mathbf{V} = 1, \mathbf{X}^i].
\end{aligned} \tag{20}$$

Consider the first mutual information term.

$$\begin{aligned}
&\mathbb{I}[\mathbf{M_P} : \Pi'^i(\mathbf{X}) \mid \mathbf{P}, \mathbf{Q}, \mathbf{R}, \mathbf{T}, \mathbf{M_T}, \mathbf{Z}, \mathbf{V} = 2, \mathbf{X}^i] \\
&= \frac{2}{\ell(\ell-1)} \sum_{p<q} \mathbb{I}[\mathbf{M}_p : \Pi'^i(\mathbf{X}) \mid \mathbf{P} = p, \mathbf{Q} = q, \mathbf{R}, \mathbf{T}, \mathbf{M_T}, \mathbf{Z}, \mathbf{V} = 2, \mathbf{X}^i] \\
&= \frac{2}{\ell(\ell-1)^2} \sum_{p<q} \sum_{r=0}^{\ell-2} \sum_{t:|t|=r} \Pr[\mathbf{T} = t] \mathbb{I}[\mathbf{M}_p : \Pi'^i(\mathbf{X}) \mid p, q, r, t, \mathbf{M}_t, \mathbf{Z}, \mathbf{V} = 2, \mathbf{X}^i] \\
&= \frac{2}{\ell(\ell-1)^2} \sum_{p<q} \sum_{r=0}^{\ell-2} \sum_{t:|t|=r} \frac{(\ell-r-2)!r!}{(\ell-2)!} \mathbb{I}[\mathbf{M}_p : \Pi'^i(\mathbf{X}) \mid p, q, r, t, \mathbf{M}_t, \mathbf{Z}, \mathbf{V} = 2, \mathbf{X}^i].
\end{aligned}$$

We can safely drop the conditioning $\mathbf{P} = p, \mathbf{R} = r, \mathbf{T} = t$ and $\mathbf{V} = 2$ in the following way. It is easy to see $\mathbf{R} = r, \mathbf{T} = t$ is implied by $\mathbf{M}_t$. $\mathbf{M}_p$ implies $\mathbf{P} = p$. Moreover, given (p, q), $\mathbf{V} = 2$ is equivalent to $\mathbf{W} = p$. So we can write,

$$\begin{aligned}
&\mathbb{I}[\mathbf{M_P} : \Pi'^i(\mathbf{X}) \mid \mathbf{P}, \mathbf{Q}, \mathbf{R}, \mathbf{T}, \mathbf{M_T}, \mathbf{Z}, \mathbf{V} = 2, \mathbf{X}^i] \\
&= \frac{2}{(\ell-1)!\ell(\ell-1)} \sum_{q} \sum_{p:p<q} \sum_{r=0}^{\ell-2} \sum_{t:|t|=r} ((\ell-r-2)!r!) \mathbb{I}[\mathbf{M}_p : \Pi'^i(X) \mid \mathbf{W} = q, \mathbf{M}_t, \mathbf{Z}, \mathbf{X}^i]. \qquad (21)
\end{aligned}$$

Similarly, the second mutual information term of Equation (20) term can be written in the following way.

$$\begin{aligned}
&\mathbb{I}[\mathbf{M_Q} : \Pi'^i(X) \mid \mathbf{P}, \mathbf{Q}, \mathbf{R}, \mathbf{T}, \mathbf{M_T}, \mathbf{Z}, \mathbf{V} = 1, \mathbf{X}^i] \\
&= \frac{2}{(\ell-1)!\ell(\ell-1)} \sum_{q} \sum_{p:p<q} \sum_{r=0}^{\ell-2} \sum_{t:|t|=r} ((\ell-r-2)!r!) \mathbb{I}[\mathbf{M}_q : \Pi'^i(\mathbf{X}) \mid \mathbf{W} = p, \mathbf{M}_t, \mathbf{Z}, \mathbf{X}^i]. \qquad (22)
\end{aligned}$$

Combining Equation (20), (21), (22), we get,

$$\begin{aligned}
&\mathbb{I}_{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2}[\mathbf{N}_{-\mathbf{V}}, \Pi'^i(\mathbf{U}) \mid \mathbf{U}^i, \mathbf{V}, \mathbf{S}] \\
&\leq \frac{1}{(\ell-1)!\ell(\ell-1)} \sum_{q'} \sum_{p':p'\neq q'} \sum_{r=0}^{\ell-2} \sum_{t:|t|=r} ((\ell-r-2)!r!) \mathbb{I}[\mathbf{M}_{p'} : \Pi'^i(X) | \mathbf{W} = q', \mathbf{M}_t, \mathbf{Z}, \mathbf{X}^i]
\end{aligned}$$

The number of permutations of $[\ell]\backslash q$ where the $r+1$th element is p' and the first r elements constitute the set t is $(\ell-r-2)!r!$. Hence we can write the previous summation as follows,

$$\begin{aligned}
&= \frac{1}{(\ell-1)!\ell(\ell-1)} \sum_{q'} \sum_{\sigma\in\mathcal{S}_{[\ell]\backslash q'}} \sum_{i\in[\ell]\backslash q'} \mathbb{I}[\mathbf{M}_{\sigma(i)} : \Pi'^i(\mathbf{X}) \mid \mathbf{M}_{\{\sigma(1),\ldots,\sigma(i-1)\}}, \mathbf{Z}, \mathbf{W} = q', \mathbf{X}^i] \\
&= \frac{1}{(\ell-1)!\ell(\ell-1)} \sum_{q'} \sum_{\sigma\in\mathcal{S}_{[\ell]\backslash q'}} \mathbb{I}[\mathbf{M}_{-q'} : \Pi'^i(\mathbf{X}) \mid \mathbf{Z}, \mathbf{W} = q', \mathbf{X}^i] \quad \text{[Using chain rule of information, Eq. (9)]} \\
&= \frac{1}{\ell-1} \sum_{q'} \frac{1}{\ell} \mathop{\mathbb{I}}_{(\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}} [\mathbf{M}_{-q'} : \Pi'^i(\mathbf{X}) \mid \mathbf{Z}, \mathbf{W} = q', \mathbf{X}^i] \\
&= \frac{1}{\ell-1} \mathop{\mathbb{I}}_{(\mathbf{X},\mathbf{M},\mathbf{Z},\mathbf{W})\sim\zeta_\ell} [\mathbf{M}_{-\mathbf{W}} : \Pi'^i(\mathbf{X}) \mid \mathbf{Z}, \mathbf{W}, \mathbf{X}^i]. \qquad (23)
\end{aligned}$$

Equation (17) can be proved almost similarly. Let's look at the LHS.

$$
\begin{aligned}
&\mathop{\mathbb{I}}_{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2}[\mathbf{U}^i_{-\mathbf{V}} : \Pi''^i(\mathbf{U}) \mid \mathbf{N},\mathbf{V},\mathbf{S}] \\
&= \mathop{\mathbb{I}}_{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}} [\mathbf{U}^i_{-\mathbf{V}} : \langle \mathbf{P},\mathbf{Q},\mathbf{Z}_{-\mathbf{P},\mathbf{Q}},\mathbf{M}_{\mathbf{T}},\mathbf{R},\mathbf{T},\mathbf{X}^i_{\bar{\mathbf{T}}\setminus\{\mathbf{P},\mathbf{Q}\}},\Pi'^i(\mathbf{X}(\mathbf{P},\mathbf{Q},\mathbf{U}))\rangle \mid \mathbf{N},\mathbf{V},\mathbf{S}] \\
&= \mathop{\mathbb{I}}_{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}} [\mathbf{U}^i_{-\mathbf{V}} : \Pi'^i(\mathbf{X}(\mathbf{P},\mathbf{Q},\mathbf{U})) \mid \mathbf{P},\mathbf{Q},\mathbf{Z},\mathbf{M}_{\mathbf{T}},\mathbf{R},\mathbf{T},\mathbf{X}^i_{\bar{\mathbf{T}}\setminus\{\mathbf{P},\mathbf{Q}\}},\mathbf{N},\mathbf{V},\mathbf{S}] \quad \text{[Lemma 3 Equation (10)]} \\
&= \mathop{\mathbb{I}}_{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}} [\mathbf{U}^i_{-\mathbf{V}} : \Pi'^i(\mathbf{X}) \mid \mathbf{P},\mathbf{Q},\mathbf{R},\mathbf{T},\mathbf{M}_{\mathbf{T}\cup\{p,q\}},\mathbf{Z},\mathbf{V},\mathbf{X}^i_{\bar{\mathbf{T}}\setminus\{\mathbf{P},\mathbf{Q}\}}] \\
&\le \mathop{\mathbb{I}}_{\substack{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2 \\ (\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}} [\mathbf{U}^i_{-\mathbf{V}} : \Pi'^i(\mathbf{X}) \mid \mathbf{P},\mathbf{Q},\mathbf{R},\mathbf{T},\mathbf{M},\mathbf{Z},\mathbf{V},\mathbf{X}^i_{\bar{\mathbf{T}}\setminus\{\mathbf{P},\mathbf{Q}\}}] \quad \text{[Lemma 3 Equation (11)]} \\
&= \frac{1}{2}\mathop{\mathbb{I}}_{(\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}[\mathbf{X}^i_{\mathbf{P}} : \Pi'^i(\mathbf{X}) \mid \mathbf{P},\mathbf{Q},\mathbf{R},\mathbf{T},\mathbf{M},\mathbf{Z},\mathbf{V}=2,\mathbf{X}^i_{\bar{\mathbf{T}}\setminus\{\mathbf{P},\mathbf{Q}\}}] \\
&+ \frac{1}{2}\mathop{\mathbb{I}}_{(\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}[\mathbf{X}^i_{\mathbf{Q}} : \Pi'^i(\mathbf{X}) \mid \mathbf{P},\mathbf{Q},\mathbf{R},\mathbf{T},\mathbf{M},\mathbf{Z},\mathbf{V}=1,\mathbf{X}^i_{\bar{\mathbf{T}}\setminus\{\mathbf{P},\mathbf{Q}\}}]. \qquad (24)
\end{aligned}
$$

Consider $\mathbf{T}' = \bar{\mathbf{T}}\setminus\{\mathbf{P},\mathbf{Q}\}$ which is distributed in the same way as $\mathbf{T}$. Here the auxiliary variable for size of $\mathbf{T}'$ is $\mathbf{R}' = (\ell-2) - \mathbf{R}$ instead of $\mathbf{R}$. $\mathbf{R}'$ is distributed in the same way as $\mathbf{R}$. We will analyze, as before, the first term of (24).

$$
\begin{aligned}
&\mathbb{I}[\mathbf{X}^i_{\mathbf{P}} : \Pi'^i(\mathbf{X}) \mid \mathbf{P},\mathbf{Q},\mathbf{R}',\mathbf{T}',\mathbf{M},\mathbf{Z},\mathbf{V}=2,\mathbf{X}^i_{\mathbf{T}'}] \\
&= \frac{2}{\ell(\ell-1)}\sum_{p<q}\mathbb{I}[\mathbf{X}^i_p : \Pi'^i(\mathbf{X}) \mid \mathbf{P}=p,\mathbf{Q}=q,\mathbf{R}',\mathbf{T}'\mathbf{M},\mathbf{Z},\mathbf{V}=2,\mathbf{X}^i_{\mathbf{T}'}] \\
&= \frac{2}{\ell(\ell-1)^2}\sum_{p<q}\sum_{r'=0}^{\ell-2}\sum_{t':|t'|=r'}\Pr[\mathbf{T}'=t']\mathbb{I}[\mathbf{X}^i_p : \Pi'^i(\mathbf{X}) \mid p,q,r',t',\mathbf{M},\mathbf{Z},\mathbf{V}=2,\mathbf{X}^i_{t'}] \\
&= \frac{2}{\ell(\ell-1)^2}\sum_{q}\sum_{p:p<q}\sum_{r'=0}^{\ell-2}\sum_{t:|t|=r'}\frac{(\ell-r'-2)!r'!}{(\ell-2)!}\mathbb{I}[\mathbf{X}^i_p : \Pi'^i(X) \mid \mathbf{W}=q,\mathbf{M},\mathbf{Z},\mathbf{X}^i_{t'}].
\end{aligned}
$$

The last equality follows by dropping the implied conditioning and introducing random variable $\mathbf{W}$ to denote the all 1 coordinate. As before we combine the second term of the Equation (24) to get the following.

$$
\begin{aligned}
&\mathbb{I}_{(\mathbf{U},\mathbf{N},\mathbf{V},\mathbf{S})\sim\zeta_2}[\mathbf{U}^i_{-\mathbf{V}} : \Pi''^i(\mathbf{U}) \mid \mathbf{N},\mathbf{V},\mathbf{S}] \\
&\le \frac{1}{(\ell-1)!\ell(\ell-1)}\sum_{\substack{(p.q):\\ p\neq q}}\sum_{r'=0}^{\ell-2}\sum_{t:|t|=r'}((\ell-r'-2)!r'!)\mathbb{I}[\mathbf{X}^i_p : \Pi'^i(\mathbf{X}) \mid \mathbf{W}=q,\mathbf{M},\mathbf{Z},\mathbf{X}^i_{t'}] \\
&= \frac{1}{(\ell-1)!\ell(\ell-1)}\sum_{q}\sum_{\sigma\in\mathcal{S}_{[\ell]\setminus q}}\sum_{i\in[\ell]\setminus q}\mathbb{I}[\mathbf{X}^i_{\sigma(i)} : \Pi'^i(\mathbf{X}) \mid X^i_{\{\sigma(1),\ldots,\sigma(i-1)\}},\mathbf{W}=q,\mathbf{Z},\mathbf{M}] \\
&= \frac{1}{(\ell-1)!\ell(\ell-1)}\sum_{q}\sum_{\sigma\in\mathcal{S}_{\ell-1}}\mathbb{I}[\mathbf{X}^i_{-\mathbf{W}} : \Pi'^i(\mathbf{X}) \mid \mathbf{Z},\mathbf{W}=q,\mathbf{M}] \\
&= \frac{1}{\ell-1}\sum_{q}\frac{1}{\ell}\mathop{\mathbb{I}}_{(\mathbf{X},\mathbf{M},\mathbf{Z})\sim\zeta_\ell\downarrow_{\mathbf{X},\mathbf{M},\mathbf{Z}}}[\mathbf{X}^i_{-\mathbf{W}} : \Pi'^i(\mathbf{X}) \mid \mathbf{Z},\mathbf{W}=q,\mathbf{M}] \\
&= \frac{1}{\ell-1}\mathop{\mathbb{I}}_{(\mathbf{X},\mathbf{M},\mathbf{Z},\mathbf{W})\sim\zeta_\ell}[\mathbf{X}^i_{-\mathbf{W}} : \Pi'^i(\mathbf{X}) \mid \mathbf{Z},\mathbf{W},\mathbf{M}]. \qquad (25)
\end{aligned}
$$

Equation (23) and Equation (25) prove the lemma. □

Lemma 11 implies the Theorem 9.

4.2 Lower bounding Disj_2

In this section we prove the following lower bound for the partial information complexity of Disj_2.

Theorem 12. $\mathsf{PIC}_{\zeta_2} = \Omega(k)$.

This, combined with Theorem 9 and Theorem 6 will imply a $\Omega(m\ell k)$ lower bound on the switched information complexity of $\mathsf{Tribes}_{m,\ell}$ which is the lower bound on $R_\delta(\mathsf{Tribes}_{m,\ell})$ we aimed for.

Notation. By $\bar{e}$ we mean the all 1 vector of size k. By $\bar{e}_{i,j}$, we mean the boolean vector of size k where all entries are 1 except the entries in index i and j. Similarly, $\bar{e}_i$ is the boolean vector the all entries are 1 except that of index i. $\Pi[i, x, m, z; \bar{e}_i]$ implies the transcript of the protocol Π on the following Disj_2 instance: the input of the first column comes from the distribution specified by $\mathbf{M} = m$, $\mathbf{Z} = z$ and $\mathbf{X}_i = x$ and the input of the second column is $\bar{e}_i$. Abusing notation slightly, $\Pi^i[x, m, z; \bar{e}_i]$ represents processor-i's view of the transcript of the protocol Π when the input of the first column comes from the distribution specified by $\mathbf{X}_i = x, \mathbf{M} = m$ and $\mathbf{Z} = z$ and the input of the second column is $\bar{e}_i$.

Hellinger distance. For probability distributions P and Q supported on a sample space Ω, the Hellinger distance between P and Q, denoted as $h(P, Q)$, is defined as,

$$h(P, Q) = \frac{1}{\sqrt{2}}||\sqrt{P} - \sqrt{Q}||_2. \tag{26}$$

Hellinger distance can also be written as follows,

$$h(P, Q)^2 = 1 - F(P, Q), \tag{27}$$

where $F(P, Q) = \sum_{\omega\in\Omega} \sqrt{P(\omega)Q(\omega)}$ is also known as Bhattacharya coefficient. From the definition it is clear to see that the Hellinger distance is a metric satisfying triangle inequality. Below we will state some facts (without proof) about Hellinger distance. Interested readers can refer to [BJKS02] for the proofs.

We will denote the statistical distance between two distributions P and Q as $\Delta(P, Q)$ and the Hellinger distance between P and Q as $h(P, Q)$.

Fact 13 (Hellinger vs. statistical distance)**.**

$$h(P, Q) \le \Delta(P, Q) \le \sqrt{2}h(P, Q). \tag{28}$$

This essentially means that the Hellinger distance is good approximation of statistical distance. The following facts gives us the necessary connection between mutual information and Hellinger distance.

Fact 14 (Hellinger vs information [Lin91])**.** *Let X be a random variable taking value in $\{x_1, x_2\}$ equally likely and let Π be a randomized protocol which takes X as input. Then,*

$$\mathbb{I}[X : \Pi(X)] \ge h^2(\Pi(x_1), \Pi(x_2)). \tag{29}$$

Fact 15. *Let Π be a δ-error protocol for function f. For inputs x and y such that $f(x) \neq f(y)$, we have,*

$$h(\Pi(x), \Pi(y)) = \frac{1 - \delta}{\sqrt{2}}. \tag{30}$$

The following lemmas will be helpful in our proof. These lemmas are straight-forward generalization of their two-party analogues.

Lemma 16. *For any randomized protocol Π computing $f : X^k \to \{0, 1\}$ and for any $x, y \in X^k$ and for some i and j,*

$$h(\Pi(x_i x_j x_{-i,j}, y_i y_j y_{-i,j})) = h(\Pi(x_i y_j x_{-i,j}, y_i x_j y_{-i,j})). \tag{31}$$

Proof. We will think of the randomized protocol Π on input (x, y) as a deterministic protocol Π' working on $(x, y, \{R_i\}_i)$ where R_i is the private random coins of player i. The first observation is that for k-party deterministic protocol, the inputs which gives rise to the same transcript π form a combinatorial rectangle $\mathbf{R}_\pi = S^1_\pi \times \cdots \times S^k_\pi$. So we have the following.

$$\begin{aligned}
\Pr_{\{R_i\}_i}[\Pi'[x, \{R_i\}_i] = \pi] &= \Pr_{\{R_i\}_i}[(x, \{R_i\}_i) \in \mathbf{R}_\pi] \\
&= \Pr_{\{R_i\}_i}\left[\bigwedge_i (x_i, R_i) \in S^i_\pi\right] \\
&= \bigwedge_i \Pr_{R_i}[(x_i, R_i) \in S^i_\pi].
\end{aligned} \tag{32}$$

Hence it immediately follows that

$$
\begin{aligned}
&1 - h^2(\Pi(x_i x_j x_{-i,j}, y_i y_j y_{-i,j})) \\
&= \sum_\pi \sqrt{\Pr_{\{R_i\}_i}[\Pi(x_i x_j x_{-i,j} = \pi]. \Pr_{\{R_i\}_i}[y_i y_j y_{-i,j} = \pi]} \\
&= \sum_\pi \Bigg[\sqrt{\Pr_{\{R_i\}_i}[(x_{-i,j}, R_{-i,j} \in \mathbf{R}_\pi^{-i,j}] \Pr_{R_i}[(x_i, R_i) \in S_\pi^i] \Pr_{R_j}[(x_j, R_j) \in S_\pi^j]} \times \\
&\qquad \sqrt{\Pr_{\{R_i\}_i}[(x_{-i,j}, R_{-i,j} \in \mathbf{R}_\pi^{-i,j}] \Pr_{R_i}[(y_i, R_i) \in S_\pi^i] \Pr_{R_j}[(y_j, R_j) \in S_\pi^j]} \Bigg] \\
&= \sum_\pi \sqrt{\Pr_{\{R_i\}_i}[\Pi(x_i y_j x_{-i,j} = \pi]. \Pr_{\{R_i\}_i}[y_i x_j y_{-i,j} = \pi]} \\
&= 1 - h^2(\Pi(x_i y_j x_{-i,j}, y_i x_j y_{-i,j})).
\end{aligned} \tag{33}
$$

□

This property of Hellinger distance is called the *k-party cut-paste property*. Another property of Hellinger distance which is required is the following.

Lemma 17. *For any randomized protocol* Π *and for any input* $x, y \in X^k$ *and for some* i *and* j*,*

$$
2h^2(\Pi(x_i x_j x_{-i,j}, y_i y_j y_{-i,j})) \geq h^2(\Pi(x_i x_j x_{-i,j}, x_i y_j y_{-i,j})) + h^2(\Pi(y_i x_j x_{-i,j}, y_i y_j y_{-i,j})). \tag{34}
$$

Proof. As before,

$$
\begin{aligned}
&(1 - h^2(\Pi(x_i x_j x_{-i,j}, x_i y_j y_{-i,j}))) + (1 - h^2(\Pi(y_i x_j x_{-i,j}, y_i y_j y_{-i,j}))) \\
&= \sum_\pi \Bigg[\sqrt{\Pr_{\{R_i\}_i}[\Pi(x_i x_j x_{-i,j} = \pi]. \Pr_{\{R_i\}_i}[x_i y_j y_{-i,j} = \pi]} + \\
&\qquad \sqrt{\Pr_{\{R_i\}_i}[\Pi(y_i x_j x_{-i,j} = \pi]. \Pr_{\{R_i\}_i}[y_i y_j y_{-i,j} = \pi]} \Bigg] \\
&= \sum_\pi \Bigg[\sqrt{\Pr_{\{R_i\}_i}[(y_{-i,j}, R_{i,j} \in \mathbf{R}_\pi^{-i,j}] \Pr_{\{R_i\}_i}[(x_{-i,j}, R_{i,j} \in \mathbf{R}_\pi^{-i,j}]} \times \\
&\qquad \sqrt{\Pr_{R_j}[(x_j, R_j) \in S_\pi^j] \Pr_{R_j}[(y_j, R_j) \in S_\pi^j]} \left(\Pr_{R_i}[(x_i, R_i) \in S_\pi^i] + \Pr_{R_i}[(y_i, R_i) \in S_\pi^i] \right) \Bigg] \\
&\geq 2 \sum_\pi \Bigg[\sqrt{\Pr_{\{R_i\}_i}[(y_{-i,j}, R_{i,j} \in \mathbf{R}_\pi^{-i,j}] \Pr_{\{R_i\}_i}[(x_{-i,j}, R_{i,j} \in \mathbf{R}_\pi^{-i,j}]} \times \\
&\qquad \sqrt{\Pr_{R_j}[(x_j, R_j) \in S_\pi^j] \Pr_{R_j}[(y_j, R_j) \in S_\pi^j]} \sqrt{\Pr_{R_i}[(x_i, R_i) \in S_\pi^i] \Pr_{R_i}[(y_i, R_i) \in S_\pi^i]} \Bigg] \\
&= 2(1 - h^2(\Pi(x_i x_j x_{-i,j}, y_i y_j y_{-i,j}))).
\end{aligned} \tag{35}
$$

□

Now we show some structural properties of coordinator model described in terms of Hellinger distance. These are generalizations of analogous properties shown in [BEO+13]. We believe, the proofs are simpler than the ones in [BEO+13]. We will make use of these structural properties later in the proof.

4.2.1 Structural properties

First we state a version of *diagonal* lemma for $\mathbf{M}$ and $\mathbf{X}^i$ which will be useful in our proof. Note that $\Pi^i(\bar{e}_{i,j}, \bar{e})$ is equivalent to $\Pi^i[1, 1, j; \bar{e}]$.

Lemma 18. *For* $i \neq j$

$$
h^2(\Pi^i[0, 0, j; \bar{e}], \Pi^i[1, 1, z; \bar{e}]) \geq \frac{1}{2} h^2(\Pi^i(\bar{e}_{i,j}; \bar{e}), \Pi^i(\bar{e}_j; \bar{e})). \tag{36}
$$

The next lemma is, as mentioned in [BEO+13], a version of *global-to-local* property of Hellinger distance in the following setting.

Lemma 19. *For $i \neq j$*

$$h^2(\Pi[i,0,0,z;\bar{e}],\Pi[i,1,0,z;\bar{e}]) = h(\Pi^i[0,0,z;\bar{e}],\Pi^i[1,0,z;\bar{e}]), \tag{37}$$

and

$$h(\Pi(\bar{e}_{i,j};\bar{e}),\Pi(\bar{e}_i;\bar{e}) = h(\Pi^i(\bar{e}_{i,j};\bar{e}),\Pi^i(\bar{e}_i;\bar{e})). \tag{38}$$

The proofs of Lemma 18 and Lemma 19 are straightforward from the analogous lemmas in [BEO+13]. We will give a simplified version of the proofs here.

Proof of Lemma 18. We have to measure the Hellinger distance of the distribution of Π^i where the inputs in the first coordinate are coming from the distribution switched by $\mathbf{M}$ and $\mathbf{Z}$. The first observation that we do is the following. In the protocol Π the input of the ith player is fixed. The protocol can be thought of as a two party protocol, where the first player is the i-th player and the second player consists of all the $k-1$ players and the coordinator. The second player, given $\mathbf{M}$ and $\mathbf{Z}$, can randomly sample the inputs of all other players participating in Π. The input of the first player, as in the case of ith player in the protocol Π is fixed. Let us call this new protocol as $\hat{\Pi}$. It is clear that the Hellinger distance in the Equation (36) remains the same if we consider $\hat{\Pi}$ instead of Π.

Now, given a two party protocol $\hat{\Pi}$, we can invoke Pythagorean lemma (two party version of Lemma 17) to imply the following.

$$\begin{aligned}
2h^2(\Pi[0,0,j;\bar{e}],\Pi[1,1,j;\bar{e}]) &= 2h^2(\hat{\Pi}[0,(0,j);\bar{e}],\hat{\Pi}[1,(1,j);\bar{e}]) \\
&\geq h^2(\hat{\Pi}[0,(0,j);\bar{e}],\hat{\Pi}[1,(0,j);\bar{e}]) \\
&\qquad + h^2(\hat{\Pi}[0,(1,j);\bar{e}],\hat{\Pi}[1,(1,j);\bar{e}]) \\
&\geq h^2(\hat{\Pi}[0,(1,j);\bar{e}],\hat{\Pi}[1,(1,j);\bar{e}]) \\
&= h^2(\Pi[\bar{e}_{i,j};\bar{e}],\hat{\Pi}[\bar{e}_j;\bar{e}]).
\end{aligned}$$

□

Proof of Lemma 19. We will make the following observations. Firstly, given any transcript τ for Π and a player i we can divide τ in three parts: $\tau_{i\leftarrow}$ which is the part of the transcript where the coordinator sends message to player i, $\tau_{i\rightarrow}$ which is the part of the transcript where the player i sends message to the coordinator and τ_{-i} where the other players and the coordinator sends message to each other.

Secondly, the following is easy to see. When the input of the player i is fixed (say to (01)) as in the case of the distribution we are interested in Eq. (37),

$$\Pr_{R,X}[\Pi=\tau] = \Pr_{R_i}[\Pi_{i\rightarrow}=\tau_{i\rightarrow} \mid X_i=(01),\Pi_{i\leftarrow}=\tau_{i\leftarrow}].\Pr_{\substack{X_{-i}\\R_{-i}}}[\Pi_{i\leftarrow}=\tau_{i\leftarrow},\Pi_{-i}=\tau_{-i} \mid \Pi_{i\rightarrow}=\tau_{i\rightarrow}]. \tag{39}$$

Similarly,

$$\Pr_{R,X}[\Pi^i=\tau^i] = \Pr_{R_i}[\Pi^i_{i\rightarrow}=\tau^i_{i\rightarrow} \mid X_i=(01),\Pi^i_{i\leftarrow}=\tau^i_{i\leftarrow}].\Pr_{R_{-i},X_{-i}}[\Pi^i_{i\leftarrow}=\tau^i_{i\leftarrow} \mid \Pi^i_{i\rightarrow}=\tau^i_{i\rightarrow}]. \tag{40}$$

So,

$$\begin{aligned}
&1-h^2(\Pi^i[0,0,z;\bar{e}],\Pi^i[1,0,z;\bar{e}]) \\
&= \sum_{\tau^i}\Bigg[\sqrt{\Pr_{R_i}[\Pi^i_{i\rightarrow}=\tau^i_{i\rightarrow} \mid X_i=(01),\Pi^i_{i\leftarrow}=\tau^i_{i\leftarrow}]\Pr_{R_i}[\Pi^i_{i\rightarrow}=\tau^i_{i\rightarrow} \mid X_i=(11),\Pi^i_{i\leftarrow}=\tau^i_{i\leftarrow}]} \\
&\qquad \Pr_{R_{-i},X_{-i}}[\Pi^i_{i\leftarrow}=\tau^i_{i\leftarrow} \mid \Pi^i_{i\rightarrow}=\tau^i_{i\rightarrow}]\Bigg] \\
&= \sum_{\tau^i}\Bigg[\sqrt{\Pr_{R_i}[\Pi^i_{i\rightarrow}=\tau^i_{i\rightarrow} \mid X_i=(01),\Pi^i_{i\leftarrow}=\tau^i_{i\leftarrow}]\Pr_{R_i}[\Pi^i_{i\rightarrow}=\tau^i_{i\rightarrow} \mid X_i=(11),\Pi^i_{i\leftarrow}=\tau^i_{i\leftarrow}]} \\
&\qquad \sum_{\tau:\tau|_i=\tau^i}\Pr_{R_{-i},X_{-i}}[\Pi_{i\leftarrow}=\tau_{i\leftarrow},\Pi_{-i}=\tau_{-i} \mid \Pi_{i\rightarrow}=\tau_{i\rightarrow}]\Bigg] \\
&= \sum_{\tau}\Bigg[\sqrt{\Pr_{R_i}[\Pi_{i\rightarrow}=\tau_{i\rightarrow} \mid X_i=(01),\Pi_{i\leftarrow}=\tau_{i\leftarrow}]\Pr_{R_i}[\Pi_{i\rightarrow}=\tau_{i\rightarrow} \mid X_i=(11),\Pi_{i\leftarrow}=\tau_{i\leftarrow}]} \\
&\qquad \Pr_{R_{-i},X_{-i}}[\Pi_{i\leftarrow}=\tau_{i\leftarrow},\Pi_{-i}=\tau_{-i} \mid \Pi_{i\rightarrow}=\tau_{i\rightarrow}]\Bigg] \\
&= 1-h^2(\Pi[i,0,0,z;\bar{e}],\Pi[i,1,0,z;\bar{e}]).
\end{aligned}$$

(38) can be proved in the similar way. □

4.2.2 Information complexity of Disj_2

Now we are ready to prove the partial information cost of Disj_2 is $\Omega(k)$. We consider processor i and fix a value $j \neq i$.

Claim 20 ([BEO+13])**.**

$$(1)\mathbb{I}[\mathbf{M}_{-\mathbf{W}} : \Pi^i \mid \mathbf{X}^i, \mathbf{Z} = j, \mathbf{W} = 2] \geq \frac{2}{3}h^2(\Pi^i[1,0,j;\bar{e}], \Pi^i[1,1,j;\bar{e}]), \tag{41}$$

$$(2)\mathbb{I}[\mathbf{X}^i_{-\mathbf{W}} : \Pi^i \mid \mathbf{M}, \mathbf{Z} = j, \mathbf{W} = 2] \geq \frac{2}{3}h^2(\Pi^i[0,0,j;\bar{e}], \Pi^i[1,0,j;\bar{e}]), \tag{42}$$

$$(3)\mathbb{I}[\mathbf{M}_{-\mathbf{W}} : \Pi^i \mid \mathbf{X}^i, \mathbf{Z} = j, \mathbf{W} = 1] \geq \frac{2}{3}h^2(\Pi^i[\bar{e};1,0,j], \Pi^i[\bar{e};1,1,j]), \tag{43}$$

$$(4)\mathbb{I}[\mathbf{X}^i_{-\mathbf{W}} : \Pi^i \mid \mathbf{M}, \mathbf{Z} = j, \mathbf{W} = 1] \geq \frac{2}{3}h^2(\Pi^i[\bar{e};0,0,j], \Pi^i[\bar{e};1,0,j]). \tag{44}$$

Proof sketch. Note that $\mathbf{M}$ takes value 0 with probability 2/3 and 1 with probability 1/3. This makes $\mathbf{M}_{-\mathbf{W}}$ a completely unbiased random variable given $\mathbf{X}^i = (11)$ and $\mathbf{Z} = j$. This lets us make the following assertion from the property of Hellinger distance (c.f. Fact 14).

$$\mathbb{I}[\mathbf{M}_{-\mathbf{W}} : \Pi^i \mid \mathbf{X}^i = (11), \mathbf{Z} = j, \mathbf{W} = 2] \geq h^2(\Pi^i[1,0,j;\bar{e}], \Pi^i[1,1,j;\bar{e}]). \tag{45}$$

Also, given $\mathbf{M} = 0$ and $\mathbf{Z} = j$, $\mathbf{X}^i$, for any $i \neq j$, is a random variable taking value between (01) and (11) uniformly. This lets us conclude the following using Fact 14.

$$\mathbb{I}[\mathbf{X}^i_{-\mathbf{W}} : \Pi^i \mid \mathbf{M} = 0, \mathbf{Z} = j, \mathbf{W} = 2] \geq h^2(\Pi^i[1,0,j;\bar{e}], \Pi^i[0,0,j;\bar{e}]). \tag{46}$$

Now, it can be checked that $\Pr[\mathbf{X}^i_{-\mathbf{W}} = (11) \mid \mathbf{Z} = j, \mathbf{W} = 2] = 2/3$ and by our construction $\Pr[\mathbf{M} = 0 \mid \mathbf{Z} = j, \mathbf{W} = 2] = 2/3$. Combining these facts with Equation (45) and (46) we can prove the claim. Other two cases can be proved similarly.

□

Using Cauchy-Schwarz and triangle inequality, we can write the following.

$$\begin{aligned}&\mathbb{I}[\mathbf{M}_{-W} : \Pi^i \mid \mathbf{X}^i, \mathbf{Z} = j, \mathbf{W}] + \mathbb{I}[\mathbf{X}^i_{-\mathbf{W}}; \Pi^i \mid \mathbf{M}, \mathbf{Z} = j, \mathbf{W}] \\ &\geq \frac{1}{3}\big[h^2(\Pi^i[1,1,j;\bar{e}], \Pi^i[0,0,j;\bar{e}]) + h^2(\Pi^i[\bar{e};1,1,j], \Pi^i[\bar{e};0,0,j])\big]\end{aligned}$$

Using Lemma 18,

$$\geq \frac{1}{6}\big[h^2(\Pi^i(\bar{e}_{i,j}.\bar{e}), \Pi^i(\bar{e}_j.\bar{e})) + h^2(\Pi^i(\bar{e}\bar{e}_{i,j}), \Pi^i(\bar{e}\bar{e}_j)\big].$$

Using Lemma 19 we get,

$$\begin{aligned}&\sum_i \mathbb{I}[\mathbf{M}_{-\mathbf{W}} : \Pi^i \mid \mathbf{X}^i, \mathbf{Z}, \mathbf{W}] + \mathbb{I}[\mathbf{X}^i_{-\mathbf{W}}; \Pi^i \mid \mathbf{M}, \mathbf{Z}, \mathbf{W}] \\ &\geq \frac{1}{6k}\sum_i \sum_{j:i\neq j} \Big[h^2(\Pi(\bar{e}_{i,j}.\bar{e}), \Pi(\bar{e}_j.\bar{e})) + h^2(\Pi(\bar{e}\bar{e}_{i,j}), \Pi(\bar{e}\bar{e}_j))\Big]\end{aligned}$$

By recounting the double summation,

$$\begin{aligned}&= \frac{1}{12k}\sum_{i\neq j} \Big[[h^2(\Pi(\bar{e}_{i,j}.\bar{e}), \Pi(\bar{e}_j.\bar{e})) + h^2(\Pi(\bar{e}_{i,j}.\bar{e}), \Pi(\bar{e}_i.\bar{e}))] \\ &\qquad + [h^2(\Pi(\bar{e}\bar{e}_{i,j}), \Pi(\bar{e}\bar{e}_j)) + h^2(\Pi(\bar{e}\bar{e}_{i,j}), \Pi(\bar{e}\bar{e}_i))]\Big]\end{aligned}$$

Using Cauchy-Schwarz & triangle inequality,

$$\geq \frac{1}{24k}\sum_{i\neq j}\Big[[h^2(\Pi(\bar{e}_i.\bar{e}),\Pi(\bar{e}_j.\bar{e}))]+[h^2(\Pi(\bar{e}\bar{e}_i),\Pi(\bar{e}\bar{e}_j))]\Big]$$

$$= \frac{1}{24k}\sum_{i\neq j}\Big[[h^2(\Pi(\bar{e}.\bar{e}),\Pi(\bar{e}_{i,j}.\bar{e}))]+[h^2(\Pi(\bar{e}\bar{e}),\Pi(\bar{e}\bar{e}_{i,j}))]\Big] \qquad \text{[Lemma 16]}$$

$$\geq \frac{1}{48k}\sum_{i\neq j}[h^2(\Pi(\bar{e}.\bar{e}_{i,j}),\Pi(\bar{e}_{i,j}.\bar{e}))] \qquad \text{[Cauchy-Schwarz \& triangle inequality]}$$

$$\geq \frac{1}{96k}\sum_{i\neq j}\Big[[h^2(\Pi(\bar{e}.\bar{e}_{i,j}),\Pi(\bar{e}_j.\bar{e}_i))+h^2(\Pi(\bar{e}_{i,j}\bar{e}),\Pi(\bar{e}_i.\bar{e}_j))]\Big] \qquad \text{[Lemma 17]}$$

$$= \frac{k-1}{384}(1-\delta)^2 \qquad \text{[Fact 15]}$$

$$= \Omega(k). \qquad (47)$$

We can write the penultimate equality because $\bar{e}.\bar{e}_{i,j}$ and $\bar{e}_{i,j}\bar{e}$ gives output 1 in Disj_2 but $\bar{e}_j.\bar{e}_i$ and $\bar{e}_i.\bar{e}_j$ gives 0.

5 Information cost & communication

In this section we will show the information complexity is right measure to lower bound by showing that the randomized communication complexity of any function f is lower bounded by the switched information complexity of f.

Theorem 21. *For any distribution μ over the inputs,*

$$R_\epsilon(\mathsf{Tribes}_{m,\ell}) = \Omega(\mathsf{IC}_\mu(\mathsf{Tribes}_{m,\ell})). \qquad (48)$$

Proof. Let us assume the random variables $(\mathbf{X},\mathbf{Z})$ is distributed according to μ and the marginal distribution on $\mathbf{X}$ is ν. Note that $\mathbb{I}_\mu[\mathbf{X};\mathbf{Y}\mid\mathbf{Z}]\leq\mathcal{H}_\mu(\mathbf{X}\mid\mathbf{Z})\leq\mathcal{H}_\nu(\mathbf{X})$. Now consider any ϵ-error protocol Π for $\mathsf{Tribes}_{m,\ell}$. We can write the following.

$$\mathbb{I}[\mathbf{X}^i:\Pi^i(\mathbf{X})\mid\mathbf{M},\mathbf{Z}]\leq\mathcal{H}(\Pi^i\mid\mathbf{M},\mathbf{Z})\leq\mathcal{H}(\Pi^i), \qquad (49)$$

and

$$\mathbb{I}[\mathbf{M}:\Pi^i(\mathbf{X})\mid\mathbf{X}^i,\mathbf{Z}]\leq\mathcal{H}(\Pi^i\mid\mathbf{X}^i,\mathbf{Z})\leq\mathcal{H}(\Pi^i). \qquad (50)$$

Now trivially $\mathcal{H}(\Pi^i)$ upper bounded by the biggest size of Π^i (Note that, Π^i is function of the random variable X) and thus the Equation (49) can be upper bounded by the biggest size of Π^i. But for each player the biggest size of his view of transcript can occur for different X. Hence we cannot upper bound the switched information complexity by the $|\Pi|$.

Instead, we use the following fact from information theory.

Lemma 22 (Theorem 5.3.1 in [CT06])**.** *The expected length L of any instantaneous q-ary code for a random variable $\mathbf{X}$ satisfies the following inequality.*

$$L\geq\frac{1}{\log q}\mathcal{H}(\mathbf{X}). \qquad (51)$$

We can make the transcript instantaneous by introducing a special delimiter . That still keeps the alphabet size constant. Hence we can write the following.

$$\mathbb{I}[\mathbf{X}^i:\Pi^i(\mathbf{X})\mid\mathbf{M},\mathbf{Z}]\leq\mathcal{H}(\Pi^i\mid\mathbf{M},\mathbf{Z})\leq\mathcal{H}(\Pi^i)\leq\log 3.\mathbb{E}(|\Pi^i|)), \qquad (52)$$

and

$$\mathbb{I}[\mathbf{M}:\Pi^i(\mathbf{X})\mid\mathbf{X}^i,\mathbf{Z}]\leq\mathcal{H}(\Pi^i\mid\mathbf{X}^i,\mathbf{Z})\leq\mathcal{H}(\Pi^i)\leq\log 3.\mathbb{E}(|\Pi^i|). \qquad (53)$$

Now we are in good shape. We will complete the proof of the lemma by the following set of equations.

$$\sum_{i\in[k]}(\mathbb{I}[\mathbf{X}^i:\Pi^i(\mathbf{X})\mid\mathbf{M},\mathbf{Z}]+\mathbb{I}[\mathbf{M};\Pi^i(\mathbf{X})\mid\mathbf{X}^i,\mathbf{Z}])\leq 2\log 3\sum_{i\in[k]}\mathbb{E}(|\Pi^i|)$$

$$= 2\log 3\mathbb{E}_x(\sum_{i\in[k]}|\Pi^i|) \qquad \text{[Linearity of expectation]}$$

$$= 2\log 3\mathbb{E}_x(|\Pi|)$$

$$= O(\max_x\{|\Pi(x)|\}). \tag{54}$$

The worst case transcript size upper bounded by the randomized communication complexity of $\mathsf{Tribes}_{m,\ell}$. This proves the theorem.

□

Combining Theorem 21, 6, 9 and 12, we can prove Theorem 1.
