

# On Space and Depth in Resolution

Alexander Razborov\*

November 1, 2016

## Abstract

We show that the total space in resolution, as well as in any other reasonable proof system, is equal (up to a polynomial and  $(\log n)^{O(1)}$  factors) to the minimum refutation depth. In particular, all these variants of total space are equivalent in this sense. The same conclusion holds for variable space as long as we penalize for excessively (that is, super-exponential) long proofs, which makes the question about equivalence of variable space and depth about the same as the question of (non)-existence of “supercritical” tradeoffs between the variable space and the proof length. We provide a partial negative answer to this question: for all  $s(n) \leq n^{1/2}$  there exist CNF contradictions  $\tau_n$  that possess refutations with variable space  $s(n)$  but such that every refutation of  $\tau_n$  with variable space  $o(s^2)$  must have double exponential length  $2^{2^{\Omega(s)}}$ . We also include a much weaker tradeoff result between variable space and depth in the opposite range  $s(n) \ll \log n$  and show that no supercritical tradeoff is possible in this range.

## 1. Introduction

The area of propositional proof complexity has seen a rapid development since its inception in the seminal paper by Cook and Reckhow [CR79]. This success is in part due to being well-connected to a number of other disciplines, and

---

\*University of Chicago, [razborov@math.uchicago.edu](mailto:razborov@math.uchicago.edu); part of this work was done while the author was at Steklov Mathematical Institute, Moscow, and at Toyota Technological Institute, Chicago. Supported by the Russian Science Foundation, grant # 14-50-00005.

one of these connections that has seen a particularly steady growth in recent years is the interplay between propositional proof complexity and practical SAT solving. As a matter of fact, SAT solvers that seem to completely dominate the landscape at the moment (like those employing conflict-driven clause learning) are inherently based on the *resolution* proof system dating back to the papers by Blake [Bla37] and Robinson [Rob65]. This somewhat explains the fact that resolution is by far the most studied system in proof complexity, even if recent developments (see e.g. the survey [BS14]) seem to be bringing the system of sum-of-squares as a serious rival<sup>1</sup>.

Most of this study concentrated on natural complexity measures of resolution proofs like size, width, depth or space and on their mutual relations; to facilitate further discussion, let us fix some notation (the reader not familiar with some or all of these is referred to Section 2 in which we give all necessary definitions). Namely, we let  $S(\tau_n \vdash 0)$ ,  $S_T(\tau_n \vdash 0)$ ,  $w(\tau_n \vdash 0)$ ,  $D(\tau_n \vdash 0)$ ,  $\text{CSpace}(\tau_n \vdash 0)$ ,  $\text{TSpace}(\tau_n \vdash 0)$  and  $\text{VSpace}(\tau_n \vdash 0)$  stand for the minimum possible size [tree-like size, width, depth, clause space, total space<sup>2</sup> and variable space, respectively].  $w(\tau_n)$  is the width of the contradiction  $\tau_n$  itself.

Let us review some prominent relations between these measures. The simulations  $w(\tau_n \vdash 0) \leq D(\tau_n \vdash 0)$  and  $\log S_T(\tau_n \vdash 0) \leq D(\tau_n \vdash 0)$  are trivial. Ben-Sasson and Wigderson [BW01] conjoined them by proving that

$$w(\tau_n \vdash 0) \leq \log S_T(\tau_n \vdash 0) + w(\tau_n). \quad (1)$$

Even more importantly, in the same paper they established the celebrated width-size relation

$$w(\tau_n \vdash 0) \leq O(n \cdot \log S(\tau_n \vdash 0))^{1/2} + w(\tau_n) \quad (2)$$

that has steadily grown into a standard method of proving lower bounds on the size of DAG resolution proofs.

In the space world, the obvious relations are  $\text{CSpace}(\tau_n \vdash 0) \leq \text{TSpace}(\tau_n \vdash 0)$  and  $\text{VSpace}(\tau_n \vdash 0) \leq \text{TSpace}(\tau_n \vdash 0)$ . Can  $\text{CSpace}(\tau_n \vdash 0)$  and  $\text{VSpace}(\tau_n \vdash 0)$  be meaningfully related to each other?

---

<sup>1</sup>It should be remarked, however, that one of the most prominent SOS lower bound technique dating back to Grigoriev’s paper [Gri01] *is* based on resolution width.

<sup>2</sup>A word of warning about terminology: it is this measure that had been called “variable space” in [ABRW02], and this usage of the term persisted in the literature for a while, see e.g. [Ben09]. But then several good arguments were brought forward as to why it is more natural to reserve the term “variable space” for its connotative meaning, and we follow this revised terminology.

In one direction this was ruled out by Ben-Sasson [Ben09, Theorem 3.9]: there are 3-CNF contradictions  $\tau_n$  with  $\text{CSpace}(\tau_n \vdash 0) = 2$  and<sup>3</sup>  $\text{VSpace}(\tau_n \vdash 0) \geq \Omega(n/\log n)$ .

Whether  $\text{CSpace}$  can be meaningfully bounded by  $\text{VSpace}$  is unknown. As will become clear soon, this question is extremely tightly connected to the content of our paper.

Let us mention several prominent and rather non-trivial results connecting “sequential” measures (size, width, depth) and “configurational”, space-oriented ones. Atserias and Dalmau [AD08] proved that

$$w(\tau_n \vdash 0) \leq \text{CSpace}(\tau_n \vdash 0) + w(\tau_n); \quad (3)$$

a simplified version of their proof was presented by Filmus et al. [FLM<sup>+</sup>15] and independently by Razborov (unpublished).

As we already observed, variable space can not be bounded in terms of clause space, but Urquhart [Urq11] proved that it can be bounded by depth:

$$\text{VSpace}(\tau_n \vdash 0) \leq D(\tau_n \vdash 0).$$

In a recent paper [Bon16], Bonacina established the following connection between width and *total* space:

$$w(\tau_n \vdash 0) \leq O(\text{TSpace}(\tau_n \vdash 0))^{1/2} + 2w(\tau_n) \quad (4)$$

that, similarly to (2), immediately opens up the possibility of proving super-linear lower bounds on the total space in a systematic way.

Finally, it should be mentioned that besides simulations there have been proven quite a great deal of separation and tradeoff results between these measures. They are way too numerous to be meaningfully accounted for here, we refer the interested readers e.g. to the survey [Nor13].

**Our contributions.** We continue this line of research and prove both simulations and tradeoff results. In the former direction, perhaps the most catchy statement we can make is that  $\text{TSpace}(\tau_n \vdash 0)$  and  $D(\tau_n \vdash 0)$  are equivalent, up to a polynomial and  $\log n$  factors (see Figure 1 below for more refined statements). This is arguably the first example when two proof

---

<sup>3</sup>Ironically (cf. Footnote 2), although this result was stated in [Ben09] for variable space, it was actually proved there only for what we call her  $\text{TSpace}$ . However, the extension to  $\text{VSpace}$  is more or less straightforward, see e.g. [BNT13].

complexity measures that are quite different in nature and have very different history turn out not only to be tightly related to each other, but actually practically equivalent.

Now, in order to discuss these simulations and their ramifications properly, we need to make up a few definitions.

For a configurational proof<sup>4</sup>  $\pi$ , let  $\mathbf{VSpace}^*(\pi) \stackrel{\text{def}}{=} \mathbf{VSpace}(\pi) \cdot \log_2 |\pi|$ ; a similar definition can be made for the total space and for the clause space although we do not need the latter in our paper. Thus, we penalize refutations in a configurational form for being *excessively* long; let us note that a similar logarithmic normalization naturally pops up in many tradeoff results, see e.g. [Ben09]. Then what we “actually” do is to show that  $\mathbf{VSpace}^*(\tau_n \vdash 0)$  is polynomially related to depth; in particular, any small variable space proof can be unfolded into a shallow sequential proof *unless* it is prohibitively long. Given this simulation, the equivalence for the total space is a simple artifact of the observation that proofs with small total space can not be too long just because there are not that many different configurations. More specifically, we have the following picture, where, for better readability,

$$\begin{array}{ccccc}
 \mathbf{VSpace} & & \leq & & \mathbf{TSpace} \leq D^2 \\
 \wedge | & & & & \wedge | \\
 D & \leq & \mathbf{VSpace}^* & \leq & \mathbf{TSpace}^* \leq D^3 \\
 & & \wedge | & & \wedge | \\
 \mathbf{VSpace}(\mathbf{VSpace} \log n + 2^{\mathbf{VSpace}}) & & & & \mathbf{TSpace}^2 \log n
 \end{array}$$

Figure 1: Simulations.

we have omitted big- $O$  and  $\tau_n \vdash 0$  everywhere. An immediate corollary is that  $\mathbf{TSpace}$ ,  $D$ ,  $\mathbf{TSpace}^*$  and  $\mathbf{VSpace}^*$  are all equivalent up to a polynomial and  $\log n$  factors, and the same applies for semantic versions of  $\mathbf{TSpace}$  and  $\mathbf{TSpace}^*$ .

The only difference between  $\mathbf{TSpace}$  and  $\mathbf{VSpace}$  is that in the first case we have a decent (that is, singly exponential) bound on the overall number of configurations of small total space. Due to the standard counting argument, this remains true for an *arbitrary* reasonable circuit class, and hence our

---

<sup>4</sup>For definitions see Section 2 below.

equivalence uniformly generalizes to the total space based on any one of them: polynomial calculus with resolution, cutting planes etc. (Theorem 3.2). All these measures are essentially depth in disguise, and hence  $n^{\Omega(1)}$  depth lower bounds *automatically* imply  $\exp(n^{\Omega(1)})$  lower bounds on the total space in all those models.

In the rest of the paper, we study the relation of variable space itself to these equivalent measures; this question was (apparently) first asked by Urquhart [Urq11]. As follows from Figure 1, this is equivalent to the following question: can the term  $2^{\text{VSpace}}$  in the upper bound on  $\text{VSpace}^*$  be really dominating or, in other words, can it be the case that the length of a configurational proof must necessarily be *super*-exponential, as long as its variable space is relatively small? Note that this in particular would imply that such a proof must mostly consist of totally non-constructive configurations so this situation may look a bit counterintuitive on the first sight. However, precisely this kind of a behavior dubbed “supercritical” tradeoffs was recently exhibited by the author [Raz16a], and several other examples have been found in [Raz16b, BN16a, BN16b].

Our most difficult result (Theorem 3.3) gives a moderate supercritical tradeoff between variable space and proof length: for any  $s = s(n) \leq n^{1/2}$ , there are  $O(1)$ -CNF contradictions  $\tau_n$  with  $\text{VSpace}(\tau_n \vdash 0) \leq s$  but such that every refutation  $\pi$  with sub-quadratic variable space  $o(s^2)$  must have length  $2^{2^{\Omega(s)}}$ . Improving the space gap from sub-quadratic to super-polynomial would establish a strong separation between the variable space and the depth, but that would probably require new techniques or at least quite a significant enhancement of ours. As a matter of fact, I am not ready even to *conjecture* that a super-polynomial gap here exists, and perhaps  $\text{VSpace}$  after all is equivalent to all other measures on Figure 1.

The proof of Theorem 3.3 is highly modular and consists of three independent reductions; we review its overall structure at the beginning of Section 5 where the statement is proven. Among previously known ingredients we can mention  $r$ -surjective functions [AR08], “hardness compression” [Raz16a] and an extensive usage of the multi-valued logic in space-oriented models [ABRW02]. One new idea that we would like to highlight is a “direct product result” Lemma 5.4; results of this sort do not seem to be too frequent in the proof complexity. We use it to amplify our length lower bound for proofs of variable space 1 (that is, consisting of multi-valued literals) to the same lower bound for proofs of larger variable space. This is precisely this

step that exponentially blows up the number of multi-valued variables and prevents us from extending this supercritical tradeoff into a super-quadratic space range.

Finally, we look into the opposite range when  $\mathbf{VSpace}(\tau_n \vdash 0)$  is very small (say, a constant) and hence the term  $2^{\mathbf{VSpace}}$  on Figure 1 becomes negligible. In this regime, the syntactic measures  $\mathbf{CSpace}$ ,  $\mathbf{TSpace}$  become constant and, by (3), the same applies to width. The author [Raz16a] proved a supercritical tradeoff between width and depth, and Berkholz and Nordström [BN16b] studied this question for width vs. space, so it seems very natural to ask what kind of tradeoffs might exist between space and depth. We prove both positive and negative results in this direction. First, we observe (Theorem 3.4) that the proof of the relation  $D \leq \mathbf{VSpace}^*$  on Figure 1 can be generalized to showing that every (semantical) refutation of constant variable space gives rise, for an arbitrary parameter  $h$ , to a configurational refutation of variable space  $O(h)$  and depth  $h^2 \cdot n^{O(1/h)}$ ; in particular, both space and depth can be made poly-logarithmic, or depth can be brought down to  $n^{1/10}$  while space still remains constant. This rules out supercritical tradeoffs in this context, at least as strong as those in [Raz16a, BN16b]. But we also show that this simulation is essentially the best possible: for the *Induction Principle*  $\tau_n = \{x_0, x_0 \rightarrow x_1, \dots, x_{n-1} \rightarrow x_n, \bar{x}_n\}$  we show that every refutation  $\pi$  with variable space  $s$  must have depth  $n^{\Omega(1/s)}$  (Theorem 3.5).

The structure of the paper corresponds to the above overview. In Section 2 we review all the necessary definitions, and in Section 3 we state our main results. The next three sections are devoted to proofs: simulation results in Section 4, the supercritical tradeoff for large space in Section 5 and small space results in Section 6. We conclude with a few remarks and open problems in Section 7.

## 2. Notation and preliminaries

We let  $[n] \stackrel{\text{def}}{=} \{1, 2, \dots, n\}$

For a Boolean function  $f$ ,  $\mathit{Vars}(f)$  is the set of variables  $f$  essentially depends on.  $f \models g$  stands for *semantical implication* and means that every assignment  $\alpha$  satisfying  $f$  satisfies  $g$  as well. If  $\tau$  and  $\tau'$  are syntactic expressions like CNFs, the semantical implication  $\tau \models \tau'$  is understood in terms of the Boolean functions these expressions represent.

A *literal* is either a Boolean variable  $x$  or its negation  $\bar{x}$ ; we will sometimes use the uniform notation  $x^\epsilon \stackrel{\text{def}}{=} \begin{cases} x & \text{if } \epsilon = 1 \\ \bar{x} & \text{if } \epsilon = 0 \end{cases}$ . A *clause* is a disjunction (possibly, empty) of literals in which no variable appears along with its negation. A *generalized clause* is either a clause or 1; the set of all generalized clauses makes a lattice in which  $\vee$  is the join operator. If  $C$  and  $D$  are clauses then  $C \leq D$  in this lattice if and only if  $C \models D$  if and only if every literal appearing in  $C$  also appears in  $D$ . We will also sometimes say that  $C$  is a sub-clause of  $D$  in this case. The empty clause will be denoted by 0, and the set of variables occurring in a clause  $C$ , either positively or negatively, will be denoted by  $\text{Vars}(C)$ , let also  $\text{Vars}(1) \stackrel{\text{def}}{=} \emptyset$ . This is consistent with the general semantic definition. The *width* of a clause  $C$  is defined as  $w(C) \stackrel{\text{def}}{=} |\text{Vars}(C)|$ .

A *CNF*  $\tau$  is a conjunction of clauses, often identified with the set of clauses it is comprised of. A CNF is a *k-CNF* if all clauses in it have width at most  $k$ . Unsatisfiable CNFs are traditionally called *contradictions*.

The *resolution proof system* operates with clauses, and it consists of the only *resolution rule*:

$$\frac{C \vee x \quad D \vee \bar{x}}{C \vee D}.$$

Two major topologies used for representing resolution proofs are *sequential* (Hilbert-style) and *configurational* (or *space-oriented*). In order to distinguish between them, we use upper-case letters  $\Pi$  for the former and lower-case  $\pi$  for the latter.

A (sequential) resolution proof  $\Pi$  is a DAG with the only target node in which all nodes are labeled by clauses, every non-source node  $v$  has fan-in 2, and the clause assigned to  $v$  can be inferred from clauses sitting at its predecessors via a single application of the resolution rule. A *resolution proof of a clause  $C$  from a CNF  $\tau$*  is a resolution proof  $\Pi$  in which all source nodes are labeled by clauses from  $\tau$ , and the target node is labeled by a sub-clause<sup>5</sup> of  $C$ . A *refutation* of a contradiction  $\tau$  is a proof of 0 from it. The *size*  $S(\Pi)$  of a sequential proof is the number of nodes, its *depth*  $D(\Pi)$  is the length of the longest path in the underlying DAG, and its *width*  $w(\Pi)$  is the minimal possible width  $w(C)$  of a clause  $C$  appearing in it. For a contradiction  $\tau$ , we let  $S(\tau \vdash 0)$ ,  $D(\tau \vdash 0)$  and  $w(\tau \vdash 0)$  denote the maximal possible value of

---

<sup>5</sup>This is a technicality that is necessary since we did not explicitly include the weakening rule.

$S(\Pi)$ ,  $D(\Pi)$  and  $w(\Pi)$ , respectively, taken over all sequential refutations  $\Pi$  of  $\tau$ .

The *configurational* (or *space-oriented*) form of propositional proofs was introduced in [ET01, ABRW02]. A *configuration*  $\mathbb{C}$  is a set of generalized clauses that can be viewed as a CNF. A *configurational proof*  $\pi$  from a CNF formula  $\tau$  is a sequence of configurations  $(\mathbb{C}_0, \dots, \mathbb{C}_T)$  in which  $\mathbb{C}_0 = \emptyset$  and every  $\mathbb{C}_t$  ( $t \in [T]$ ) is obtained from  $\mathbb{C}_{t-1}$  by one of the following rules:

**AXIOM DOWNLOAD.**  $\mathbb{C}_t = \mathbb{C}_{t-1} \cup \{A\}$ , where  $A \in \tau$ ;

**INFERENCE.**  $\mathbb{C}_t = \mathbb{C}_{t-1} \cup \{C\}$  for some  $C$  inferrable by a single application of the resolution rule from the clauses in  $\mathbb{C}_{t-1}$ .

**ERASURE.**  $\mathbb{C}_t \subseteq \mathbb{C}_{t-1}$ .

$\pi$  is a (configurational) refutation of  $\tau$  if  $0 \in \mathbb{C}_T$ .  $T$  is the *length* of  $\pi$ , denoted by  $|\pi|$ .

The *clause space* of a configuration  $\mathbb{C}$  is  $|\mathbb{C}|$ , its *total space*  $\mathbf{TSpace}(\mathbb{C})$  is  $\sum_{C \in \mathbb{C}} w(C)$ , and its *variable space*  $\mathbf{VSpace}(\mathbb{C})$  is  $|\bigcup_{C \in \mathbb{C}} \mathit{Vars}(C)|$ . The *clause [total] space*  $\mathbf{CSpace}(\pi)$  [ $\mathbf{TSpace}(\pi)$ , respectively] of a configurational proof  $\pi$  is the maximal clause [total, respectively] space of all its configurations, and if  $\tau$  is a contradiction, then  $\mathbf{CSpace}(\tau \vdash 0)$  [ $\mathbf{TSpace}(\tau \vdash 0)$ ] is the minimum value of  $\mathbf{CSpace}(\pi)$  [ $\mathbf{TSpace}(\pi)$ , respectively], where the minimum is taken over all configurational refutations  $\pi$  of  $\tau$ .

Variable space  $\mathbf{VSpace}(\tau_n \vdash 0)$  can be of course defined analogously, but since this measure is inherently semantical, we prefer to stress this fact by giving a separate, and more robust, definition below.

**Definition 2.1** Let  $\tau$  be an arbitrary set of Boolean constraints. For a set  $V$  of variables, we let

$$\tau[V] \stackrel{\text{def}}{=} \bigwedge \{C \mid C \in \tau \wedge \mathit{Vars}(C) \subseteq V\}.$$

A *semantical proof*  $\pi$  from  $\tau$  is a sequence of Boolean functions  $(f_0, \dots, f_1, \dots, f_T)$  such that  $f_0 \equiv 1$  and for every  $t \in T$ ,

$$f_{t-1} \wedge \tau[\mathit{Vars}(f_{t-1}) \cup \mathit{Vars}(f_t)] \models f_t. \quad (5)$$

$T$  is again the *length* of  $\pi$ , denoted by  $|\pi|$ , and  $\pi$  is a *semantical refutation* if  $f_T \equiv 0$ .  $\mathbf{VSpace}(\pi) \stackrel{\text{def}}{=} \max_{0 \leq t \leq T} |\mathit{Vars}(f_t)|$  and  $\mathbf{VSpace}(\tau \vdash 0)$  is the minimum value of  $\mathbf{VSpace}(\pi)$  taken over all semantical refutations  $\pi$  of  $\tau$ .

In this definition we have combined all three rules (AXIOM DOWNLOAD, INFERENCE and ERASURE) into one. Every configurational proof turns into a semantical proof of (at most) the same variable space if we replace all configurations in it by the Boolean functions they represent. Hence  $\mathbf{VSpace}(\tau \vdash 0)$  never exceeds its syntactical variant, and in the other direction (when  $\tau$  is actually a CNF), they may differ by at most a factor of 2 simply by expanding all semantical refutations (5) into brute-force resolution derivations never leaving the set of variables  $\mathit{Vars}(f_{t-1}) \cup \mathit{Vars}(f_t)$ .

This purely semantical model also provides a handy uniform way to talk about semantical analogues of more sophisticated space complexity measures. Namely, let  $\mathcal{C}$  be a circuit class equipped with a complexity measure  $\mu(C)$  ( $C \in \mathcal{C}$ ). Then  $\mu$  gives rise to the complexity measure on Boolean functions in a standard way:  $\mu_{\mathcal{C}}(f)$  is the minimum value of  $\mu_C$  taken over all circuits  $C \in \mathcal{C}$  computing  $f$ . For a semantical refutation  $\pi$ , let us define  $\mu_{\mathcal{C}} - \mathbf{Space}(\pi) \stackrel{\text{def}}{=} \max_{0 \leq t \leq T} \mu_{\mathcal{C}}(f_t)$  and then  $\mu_{\mathcal{C}} - \mathbf{Space}$  as usual.

**Examples.** Semantical analogues of clause and total space studied in the literature before correspond to the case when  $\mathcal{C}$  consists of all CNFs, and the measures  $\mu_{\mathcal{C}}$  are the number of clauses or overall size, respectively. Semantical analogues of, say, cutting planes space or PCR space are also straightforward in this language.

Finally, we need several mixed measures. We let

$$\begin{aligned} \mathbf{TSpace}^*(\pi) &\stackrel{\text{def}}{=} \mathbf{TSpace}(\pi) \cdot \log_2 |\pi|, \\ \mathbf{VSpace}^*(\pi) &\stackrel{\text{def}}{=} \mathbf{VSpace}(\pi) \cdot \log_2 |\pi|, \\ \mu_{\mathcal{C}} - \mathbf{Space}^*(\pi) &\stackrel{\text{def}}{=} \mu_{\mathcal{C}} - \mathbf{Space}(\pi) \cdot \log_2 |\pi|, s(\pi) \cdot \log_2 |\pi|, \end{aligned}$$

and then we define  $\mathbf{TSpace}^*(\tau \vdash 0)$ ,  $\mathbf{VSpace}^*(\tau \vdash 0)$  and  $\mu_{\mathcal{C}} - \mathbf{Space}^*(\tau \vdash 0)$  as usual ( $\mathbf{CSpace}^*(\tau \vdash 0)$  can be also defined likewise, but we do not need it in this paper).

**Definition 2.2** For a configurational proof  $\pi = (\mathbb{C}_0, \mathbb{C}_1, \dots, \mathbb{C}_T)$ , define integer valued *depth functions*  $D_t$  on  $\mathbb{C}_t$  by induction on  $t$ . Since  $\mathbb{C}_0$  is empty, there is nothing to define. Let  $t > 0$ , assume that  $C \in \mathbb{C}_t$  and that  $D_{t-1}$  is already defined. If  $C \in \mathbb{C}_{t-1}$ , we simply let  $D_t(C) \stackrel{\text{def}}{=} D_{t-1}(C)$ . If  $A \in \tau$  in the AXIOM DOWNLOAD RULE then  $D_t(A) \stackrel{\text{def}}{=} 0$ . If  $C$  is obtained from  $C', C'' \in \mathbb{C}_{t-1}$  via the resolution rule, we let

$$D_t(C) \stackrel{\text{def}}{=} \max(D_{t-1}(C'), D_{t-1}(C'')) + 1.$$

Finally, the *depth*  $D(\pi)$  of a configurational refutation  $\pi$  is defined as  $D_T(0)$ .

### 3. Main results

As all our results were discussed at length in the introduction, here they are listed more or less matter-of-factly.

In order to improve readability, in our first theorem 3.1 we omit the argument  $\tau_n \vdash 0$  throughout ( $\tau_n$  is an arbitrary contradiction in  $n$  variables), and also we write  $f \preceq g$  for  $f \leq O(g)$ .

**Theorem 3.1** *For the proof-complexity measures  $D$ , TSpace, VSpace, TSpace\*, VSpace\* introduced in Section 2 we have the following simulations:*

$$\begin{array}{ccccc}
 \text{VSpace} & & \preceq & & \text{TSpace} & \preceq & D^2 \\
 \wedge | & & & & \wedge | & & \wedge | \\
 D & \preceq & & \text{VSpace}^* & \preceq & \text{TSpace}^* & \preceq & D^3 \\
 & & & \wedge | & & \wedge | & & \\
 \text{VSpace}(\text{VSpace} \log n + 2^{\text{VSpace}}) & & & & & \text{TSpace}^2 \log n. & & 
 \end{array}$$

**Theorem 3.2** *Let  $\mathcal{C}$  be any circuit class that includes CNFs, and let  $\mu_{\mathcal{C}}$  be any complexity measure on  $\mathcal{C}$  that is intermediate between the number of input variables and the circuit size of  $C \in \mathcal{C}$ . Then  $\mu_{\mathcal{C}} - \text{Space}(\tau_n \vdash 0)$  is equivalent, up to a polynomial and  $\log n$  factors to  $D(\tau_n \vdash 0)$  (and hence to all other measures in Theorem 3.1 except, possibly, VSpace).*

**Theorem 3.3** *Let  $s = s(n) \leq n^{1/2}$  be an arbitrary parameter. Then there exists a CNF  $\tau_n$  with  $\text{VSpace}(\tau_n \vdash 0) \leq s$  but such that for any semantical refutation  $\pi$  of  $\tau_n$  with  $\text{VSpace}(\pi) \leq o(s^2)$  we have  $|\pi| \geq \exp(\exp(\Omega(s)))$ .*

The next result is a variation on the simulation  $D \preceq \text{VSpace}^*$  in Theorem 3.1.

**Theorem 3.4** *Assume that a contradiction  $\tau$  possesses a semantical refutation  $\pi$  with  $\text{VSpace}(\pi) = s$  and  $|\pi| = S$ , and let  $h \geq 1$  be an arbitrary parameter. Then  $\tau$  also has a configurational refutation  $\pi'$  with  $\text{VSpace}(\pi') \leq O(sh)$  and  $D(\pi') \leq O(sh^2 \cdot S^{1/h})$ .*

**Theorem 3.5** *Let  $\tau_n = \{x_0, \bar{x}_0 \vee \bar{x}_1, \bar{x}_1 \vee x_2, \dots, \bar{x}_{n-1} \vee x_n, \bar{x}_n\}$ . Then for every configurational refutation  $\pi$  from  $\tau_n$  we have the bound*

$$D(\pi) \geq \Omega\left(n^{1/\text{VSpace}(\pi)}\right).$$

## 4. Proofs of simulations

In this short section we prove Theorems 3.1, 3.2.

**Proof of Theorem 3.1.** The square

$$\begin{array}{ccc} \text{VSpace} & \leq & \text{TSpace} \\ & & \wedge \\ \text{VSpace}^* & \leq & \text{TSpace}^* \end{array}$$

is obvious.

$\text{VSpace}(\tau \vdash 0) \leq D(\tau \vdash 0)$  is [Urq11, Theorem 6.1(1)].

$\text{TSpace}(\tau \vdash 0) \leq D(\tau \vdash 0)(D(\tau \vdash 0) + 1)$  **and**  $\text{TSpace}^*(\tau \vdash 0) \leq D(\tau \vdash 0)(D(\tau \vdash 0) + 1)^2$ .

This is a minor variation on [ET01, Theorem 2.1]. Indeed, let  $\Pi$  be a refutation of a contradiction  $\tau$  with  $D(\Pi) = d$ , then w.l.o.g. we can assume that  $\Pi$  is in a tree-like form. Also,  $w(\Pi) \leq d$  since every variable in the clause at a node  $v$  must be resolved on the path from  $v$  to the target (root) node. We now consider the standard pebbling of the underlying tree with  $(d + 1)$  pebbles and the resulting configuration refutation  $\pi = (\mathbb{C}_0, \mathbb{C}_1, \dots, \mathbb{C}_T)$ , as in [ET01].  $|\mathbb{C}_t| \leq d + 1$ , every clause in  $\pi$  has width  $\leq d$  (due to the above remark) and  $T \leq 2^{d+1}$ . Both claims follow.

$\text{TSpace}^*(\tau_n \vdash 0) \leq 2 \log_2(2n + 1) \text{TSpace}(\tau_n \vdash 0)^2$  **and**  $\text{VSpace}^*(\tau_n \vdash 0) \leq \text{VSpace}(\tau_n \vdash 0) \left( \text{VSpace}(\tau_n \vdash 0) \log_2 n + 2^{\text{VSpace}(\tau_n \vdash 0)} \right)$ .

Both bounds follow from the observation that a configurational refutation (be it syntactic or semantic) can w.l.o.g. be assumed not to contain repeated configurations. Now, we estimate the overall number of configurations  $\mathbb{C} = (C_1, \dots, C_k)$  with total space  $\leq s$  by encoding them as a string  $C_1 \# C_2 \# \dots \# C_k \# \dots$  of length  $2s$  in which the clauses  $C_i$  are written down simply as sequences of literals. We conclude that the overall number of different configurations  $\mathbb{C}$  of total space  $\leq s$  is bounded by  $(2n + 1)^{2s}$ , which

gives us the first statement. Likewise, the overall number of Boolean functions  $f$  with  $|Vars(f)| \leq s$  is bounded by  $\binom{n}{s} 2^{2^s} \leq n^s 2^{2^s}$ , and this gives us the second statement.

$$D(\tau \vdash 0) \leq 2\mathbf{VSpace}^*(\tau \vdash 0).$$

This is by standard binary search. Let  $\pi = (f_0, f_1, \dots, f_T)$  be a semantical refutation from  $\tau$  minimizing  $\mathbf{VSpace}^*(\pi)$ , and let  $s \stackrel{\text{def}}{=} \mathbf{VSpace}(\pi)$ . We prove by induction on  $d$  that for every  $0 \leq a < b \leq T$  with  $b - a \leq 2^d$  and for any clause  $C$  in the straightforward CNF expansion of the implication  $f_a \rightarrow f_b$  (that is to say, for every clause  $C$  with  $Vars(C) = Vars(f_a) \cup Vars(f_b)$  and  $(f_a \rightarrow f_b) \models C$ ) we have  $D(\tau \vdash C) \leq 2s(d + 1)$ .

**Induction base**  $d = 0$ ,  $b = a + 1$ .

We have  $f_a \wedge \tau[Vars(f_a) \cup Vars(f_{a+1})] \models f_{a+1}$ , hence  $\tau[Vars(f_a) \cup Vars(f_{a+1})] \models (f_a \rightarrow f_{a+1}) \models C$ . Since  $|Vars(f_a) \cup Vars(f_{a+1})| \leq 2s$ , we can realize the latter semantical refutation by a resolution refutation of depth  $\leq 2s$ .

**Inductive step:**  $d \geq 1$ ,  $2 \leq b - a \leq 2^d$ .

Pick  $c$  with  $a < c < b$  such that  $c - a, b - c \leq 2^{d-1}$ . Then  $C$  has an obvious resolution proof of depth  $|Vars(f_c) \setminus (Vars(f_a) \cup Vars(f_b))| \leq s$  from clauses  $\tilde{C}$  appearing in the CNF expansions of  $f_a \rightarrow f_c$  and  $f_c \rightarrow f_b$ . Since  $D(\tau \vdash \tilde{C}) \leq (d - 1)s$  for any such clause by the inductive assumption, the inductive step follows.

In particular, setting  $d = \log_2 T$ ,  $a = 0$ ,  $b = T$ ,  $C = 0$ , we conclude that  $D(\tau \vdash 0) \leq (2s) \log_2 T \leq 2\mathbf{VSpace}^*(\pi)$ .  $\blacksquare_{\text{THEOREM 3.1}}$

**Proof of Theorem 3.2.** It is now straightforward. Since  $\mathcal{C}$  includes all CNFs and  $\mu_{\mathcal{C}}$  does not exceed the circuit size that in the case of a CNF is bounded by the total space, we have  $\mu_{\mathcal{C}} - \mathbf{Space}(\tau \vdash 0) \leq O(\mathbf{TSpace}(\tau \vdash 0) \cdot \log n)$ . On the other hand, since  $\mu_{\mathcal{C}}$  is bounded from below by the number of essential variables, for every semantical proof  $\pi$  we have  $\mathbf{VSpace}(\pi) \leq s \stackrel{\text{def}}{=} \mu_{\mathcal{C}} - \mathbf{Space}(\pi)$ . If  $\pi$  in addition is minimal, then the length is bounded by the overall number of circuits  $C$  in  $\mathcal{C}$  that satisfy  $\mu_{\mathcal{C}}(C) \leq s$  and hence, using again the condition on  $\mu_{\mathcal{C}}$ , have size  $\leq s$ . Since the number of circuits of size  $s$  is bounded (to be on the safe side) by  $n^{O(s)}$ , the bound  $\mathbf{VSpace}^*(\pi) \leq O(s^2 \log n)$  follows. As  $\mathbf{VSpace}^*$  and  $\mathbf{TSpace}$  are equivalent up to a polynomial and  $\log n$  factors, the same holds for  $\mu_{\mathcal{C}} - \mathbf{Space}$ .  $\blacksquare_{\text{THEOREM 3.2}}$

## 5. A supercritical tradeoff between variable space and length

In this section we prove Theorem 3.3. While it is our most difficult result, its proof naturally splits into three fairly independent parts, and we present it in this modular way, interlaced with necessary definitions. Like in [ABRW02, Section 4.3], it will be very convenient to work in the multi-valued setting.

**Definition 5.1** (cf. [ABRW02, Definitions 4.5-4.7]). Let  $D$  be a finite domain. Instead of Boolean variables, we consider  $D$ -valued variables  $X_i$  ranging over the domain  $D$ . A *multi-valued function*  $f(X_1, \dots, X_n)$  is a mapping from  $D^n$  to  $\{0, 1\}$ . Since the image here is still Boolean, the notions of a (multi-valued) satisfying assignment  $\alpha \in D^n$  and the semantical implication  $f \models g$  are generalized to the multi-valued logic straightforwardly. So does the definition of the set of essential variables  $Vars(f)$ .

A ( $D$ -valued) *literal* is an expression of the form  $X^P$ , where  $X$  is a ( $D$ -valued) variable and  $P \subseteq D$  is such that  $P \neq \emptyset$  and  $P \neq D$ . Allowing here also  $D = 0$  or  $D = P$ , we obtain the definition of a *generalized ( $D$ -valued) literal*. A generalized literal  $X^P$  is semantically interpreted by the characteristic function of the set  $P$ .  $X^Q$  is a *weakening* of  $X^P$  if  $P \subseteq Q$  or, equivalently,  $X^P \models X^Q$ .

A  $D$ -valued *clause* [term] is a conjunction of multi-valued literals corresponding to pairwise distinct variables. A *constraint satisfaction problem* (CSP) is simply a set of arbitrary multi-valued functions called in this context “constraints”. The *width* of a constraint  $C$  is again  $|Vars(C)|$ , and a CSP is an  $k$ -CSP if all constraints in it have width  $\leq k$ . A *semantical  $D$ -valued refutation* from a multi-valued CSP  $\eta$  and its variable space are defined exactly as in the Boolean case.

Our starting point is the following weak supercritical tradeoff. Before stating it, let us remind that according to our conventions, proofs of variable space 1 make perfect sense and are precisely those in which all configurations are representable by generalized literals.

**Lemma 5.2** *For any finite domain  $D$ , there exists a  $D$ -valued 2-CSP  $\eta$  in four variables such that  $\eta$  is refutable in variable space 1, but any such refutation  $\pi$  must have length  $\geq \exp(D^{\Omega(1)})$ .*

The next (crucial, and most technical) step is to amplify the lower bound of 2 on the variable space of moderately short refutations while still keeping the condition  $\mathbf{VSpace}(\tau \vdash 0) = 1$ . For that we need a carefully designed iterative construction. It is this step that blows up the number of variables exponentially, and this is the primary reason why our gap in Theorem 3.3 is only quadratic.

Let us begin with a few combinatorial definitions (they will not be needed outside of the proof of Lemma 5.4). The *concatenation* of two words  $u$  and  $v$  in the same alphabet will be denoted by  $uv$ , and  $|u|$  is the length of the word  $u$ .  $u$  is a *prefix* of  $v$ , denoted by  $u \leq v$  if  $v = uw$  for another (possibly, empty) word  $w$ .

For integer parameters  $h, \ell \geq 0$  that will be fixed throughout the proof, we let  $V \stackrel{\text{def}}{=} \{(i_1, \dots, i_h) \mid i_\nu \in [\ell]\}$  be the set of all words of length  $h$  in the alphabet  $[\ell]$ . The set  $V$  will be alternately viewed as the set of all leaves of an  $\ell$ -ary tree of height  $h$ , and it is equipped with the natural ultrametric:  $\rho(u, v)$  is equal to  $h$  minus the length of the longest common prefix of  $u$  and  $v$ . This geometric view of  $V$  as an ultrametric space will be our preferred interpretation in the proof of Lemma 5.4.

We let  $V^+$  be the set of all words  $u$  in the same alphabet  $\ell$  such that  $1 \leq |u| \leq h$ . Its elements correspond to *non-root* vertices of the tree. Conveniently, elements of  $V^+$  can be also naturally identified with non-trivial (that is, non-empty and different from the whole space  $V$ ) balls in the ultrametric  $\rho$ .

For notational simplicity we confine the following definition to CSPs in the same number of variables  $\ell$ . Its generalization to arbitrary CSPs is straightforward.

**Definition 5.3** Let  $D_1, \dots, D_h$  be pairwise disjoint finite sets,  $D \stackrel{\text{def}}{=} D_1 \dot{\cup} \dots \dot{\cup} D_h$ , and let  $\eta_1(X_1, \dots, X_\ell), \dots, \eta_h(X_1, \dots, X_\ell)$  be CSPs, where  $\eta_d$  is  $D_d$ -valued. We define their *lexicographic product*  $\eta_h \cdot \eta_{h-1} \cdot \dots \cdot \eta_1$  that will be a  $D$ -valued CSP in the variables  $(X_v \mid v \in V)$  as follows.

1. For  $1 \leq d \leq h - 1$ , let  $\text{Con}_d(X, Y)$  be the conjunction of the formulas  $X^{\{a\}} \equiv Y^{\{a\}}$ , where  $a \in D_{d+1} \cup \dots \cup D_h$ . We include into  $\eta_h \cdot \eta_{h-1} \cdot \dots \cdot \eta_1$  the constraints  $\text{Con}_d(X_u, X_v)$  for all  $u, v \in V$  with  $\rho(u, v) = d$ .

Informally, if one of the variables  $X_u, X_v$  was assigned at a level<sup>6</sup> where

---

<sup>6</sup>We enumerate levels in the tree from leaves to the root!

$u$  and  $v$  still agree, then the other variable must be also assigned to the same value. Otherwise, the constraint is vacuous.

2. Let  $C(X_{i_1}, \dots, X_{i_w})$  be a ( $D_d$ -valued) constraint in  $\eta_d$ . We let the formula  $\widehat{C}(Y_1, \dots, Y_w)$  of the  $D$ -valued logic be defined as

$$\bigwedge_{\nu=1}^w Y_\nu^{D_d} \implies C(Y_1, \dots, Y_w) \quad (6)$$

(the right-hand side here makes sense due to the premise  $\bigwedge_{\nu=1}^w Y_\nu^{D_d}$ ). We add to  $\eta_h \cdot \eta_{h-1} \dots \eta_1$  all axioms of the form  $\widehat{C}(X_{u_1}, \dots, X_{u_w})$  as long as  $\rho(u_\nu, u_\mu) = d$  for all  $\nu \neq \mu$  (in particular,  $u_1, \dots, u_w$  share a common prefix of length  $h - d$ ) and  $(u_\nu)_{h-d+1} = i_\nu$  ( $1 \leq \nu \leq w$ ).

Informally, if  $u_1, \dots, u_w$  are all children of the same node branching in pairwise different directions and *all* variables  $X_{u_1}, \dots, X_{u_w}$  are assigned at exactly this branching level (i.e., in  $D_d$ ), then their assignments must satisfy all applicable constraints in  $\eta_d$ . If at least one of these variables is assigned outside of  $D_d$ , the constraint is vacuous.

Note that if all  $\eta_1, \dots, \eta_h$  are 2-CSP (which is the case we are mostly interested in), then their lexicographic product is also a 2-CSP.

**Remark 1** One good way to interpret Definition 5.3 is by introducing auxiliary ( $D_d \cup \{*\}$ )-valued variables  $Y_u$  ( $u \in V^*$ ,  $|u| = h - d + 1$ ) with the intended meaning

$$Y_u = \begin{cases} X_v & \text{if } X_v \in D_d \text{ (} v \in V, v \geq u \text{)} \\ * & \text{if } X_v \notin D_d. \end{cases} \quad (7)$$

Then the first group of axioms in Definition 5.3 simply asserts that the right-hand side in (7) is well-defined, that is does not depend on the choice of  $v \geq u$ . The second group of axioms simplifies to  $\bigwedge_{\nu=1}^w (Y_\nu \neq *) \implies C(Y_{u_1}, \dots, Y_{u_w})$  for all  $u \in V^*$  with  $|u| = h - d$ .

While this approach is syntactically quite attractive, we do not see how we can use it for a simple but powerful reason: we would also need to add the totality axioms

$$\bigvee_{u \leq v} (Y_u \neq *) \text{ (} v \in V \text{)} \quad (8)$$

asserting that all  $X_v$  are well-defined, and these are prohibitively wide for our purposes. In a sense, our  $D$ -valued variables  $X_v$  can be viewed as *extension variables* allowing us to reduce the width in the axioms (8).

**Lemma 5.4** *Assume that  $\eta_1(X_1, \dots, X_\ell), \dots, \eta_h(X_1, \dots, X_\ell)$  are multi-valued 2-CSPs such that  $\text{VSpace}(\eta_d \vdash 0) = 1$  ( $d \in [h]$ ) but any refutation  $\pi$  of  $\eta_d$  with  $\text{VSpace}(\pi) = 1$  must have length  $\geq T$ , and let  $\eta \stackrel{\text{def}}{=} \eta_h \cdot \dots \cdot \eta_1$  be their lexicographic product. Then  $\text{VSpace}(\eta \vdash 0) = 1$  (in particular,  $\eta$  is a contradiction), but any its refutation  $\pi$  with  $\text{VSpace}(\pi) \leq h/2 - 1$  must also have length  $\geq T$ .*

Finally, we need to transfer the tradeoff resulting from Lemmas 5.2, 5.4 to the Boolean setting. This involves two different tasks: the conversion per se and a variable compression in the style of [Raz16a] that is certainly needed here since the number of variables in the lexicographic product is huge (exponential in  $h$ ). We will combine both tasks into a single statement, but first we need a few definitions.

**Definition 5.5** ([AR08]) A function  $g : \{0, 1\}^s \rightarrow D$  is  $r$ -surjective if for any restriction  $\rho$  assigning at most  $r$  variables, the restricted function  $g|_\rho$  is surjective.

**Definition 5.6** (cf. [Raz16a]) Let  $A$  be an  $m \times n$  0-1 matrix in which every row has precisely  $s$  ones and  $g : \{0, 1\}^s \rightarrow D$  be a function. Let  $g[A] : \{0, 1\}^n \rightarrow D^m$  be naturally defined as

$$g[A](x_1, \dots, x_n)(i) \stackrel{\text{def}}{=} g(x_{j_1}, \dots, x_{j_s}),$$

where  $j_1 < j_2 < \dots < j_s$  is the enumeration of ones in the  $i$ th row of  $A$ . For a  $D$ -valued Boolean function  $f : D^m \rightarrow \{0, 1\}$ , we let the Boolean function  $f[g, A] : \{0, 1\}^n \rightarrow \{0, 1\}$  be the composition  $f \circ g[A]$ . Finally, for a  $D$ -valued CSP  $\eta(Y_1, \dots, Y_m)$ , we let  $\eta[g, A] \stackrel{\text{def}}{=} \{C[g, A] \mid C \in \eta\}$ .

**Definition 5.7** Let  $A$  be a  $m \times n$  0-1 matrix. For  $i \in [m]$ , let

$$J_i(A) \stackrel{\text{def}}{=} \{j \in [n] \mid a_{ij} = 1\}$$

be the set of all ones in the  $i$ th row. For a set of rows  $I \subseteq [m]$ , the *boundary*  $\partial_A(I)$  of  $I$  is defined as

$$\partial_A(I) \stackrel{\text{def}}{=} \{j \in [n] \mid |\{i \in I \mid j \in J_i(A)\}| = 1\},$$

i.e., it is the set of columns that have *precisely* one 1 in their intersections with  $I$ .  $A$  is an  $(r, c)$ -boundary expander if  $|\partial_A(I)| \geq c|I|$  for every set of rows  $I \subseteq [m]$  with  $|I| \leq r$ .

**Lemma 5.8** *Let  $A$  be an  $m \times n$   $(2h, \frac{3}{4}s)$ -boundary expander in which every row has precisely  $s$  elements. Let  $D$  be a finite domain,  $\eta(Y_1, \dots, Y_m)$  be a  $D$ -valued  $h$ -CSP and  $g : \{0, 1\}^s \rightarrow D$  be an  $(3s/4)$ -surjective function. Assume that there exists a semantic (Boolean) refutation  $\pi$  from  $\eta[g, A]$  with  $\mathbf{VSpace}(\pi) \leq (hs)/16$ . Then there exists a  $D$ -valued refutation  $\hat{\pi}$  of  $\eta$  with  $\mathbf{VSpace}(\hat{\pi}) \leq h$  and  $|\hat{\pi}| = |\pi|$ .*

Before we embark on the proofs of Lemma 5.2, 5.4 and 5.8, let us do something simpler, namely assemble from them the proof of the main result of this section.

**Proof of Theorem 3.3.** We are given a function  $s = s(n) \leq n^{1/2}$ . We let  $h \stackrel{\text{def}}{=} \lfloor \epsilon s \rfloor \leq \epsilon n/s$ , where  $\epsilon$  is a sufficiently small constant. Then, by [Raz16a, Lemma 2.2] there exists an  $(2h, \frac{3}{4}s)$ -boundary expander with  $m = 4^h$  rows each having exactly<sup>7</sup>  $s$  ones. Next, a standard calculation shows that if  $s$  is sufficiently large (that we can clearly assume w.l.o.g.) a random function  $g : \{0, 1\}^s \rightarrow D$  is  $(3s/4)$  surjective for  $|D| = 2^{s/8}$ , with probability  $1 - o(1)$ . Pick any such  $g$  arbitrarily, and split  $D$  into  $h$  nearly equal parts,  $D = D_1 \dot{\cup} \dots \dot{\cup} D_h$ . Let  $\eta_d$  be the  $D_d$ -valued 2-CSP in four variables guaranteed by Lemma 5.2, that is such that  $\mathbf{VSpace}(\eta_d \vdash 0) = 1$  but any its refutation  $\pi$  with  $\mathbf{VSpace}(\pi) = 1$  must have length  $\geq \exp(|D_d|^{\Omega(1)}) \geq \exp(\exp(\Omega(s)))$ . Let  $\eta \stackrel{\text{def}}{=} \eta_h \cdot \dots \cdot \eta_1$ . The  $D$ -valued 2-CSP  $\eta$  has  $m = 4^h$  variables, say,  $Y_1, \dots, Y_m$  and still satisfies  $\mathbf{VSpace}(\eta \vdash 0) = 1$  but now any its refutation  $\hat{\pi}$  with  $\mathbf{VSpace}(\hat{\pi}) \leq h/2 - 1$  has length  $\exp(\exp(\Omega(s)))$ . The desired contradiction  $\tau_n$  will be  $\eta[g, A]$ .

First of all,  $\tau_n$  has a semantical refutation with variable space  $\leq s$ . It is obtained simply by taking a  $D$ -valued refutation of  $\eta$  with variable space 1 (that is, consisting of generalized literals) and applying the operator  $Y_i^P \mapsto Y_i^P[g, A]$  to its configurations. On the other hand, applying Lemma 5.8 in the contrapositive form, every Boolean refutation  $\pi$  from  $\eta_g[A]$  with  $\mathbf{VSpace}(\pi) \leq (h/2 - 1)s/16$  must have length  $\geq \exp(\exp(\Omega(s)))/\exp(O(h))$ . As  $h = \Theta(s)$ , this is  $\exp(\exp(\Omega(s)))$ . ■THEOREM 3.3

It remains to prove Lemma 5.2, 5.4 and 5.8.

<sup>7</sup>Literally, [Raz16a, Lemma 2.2] gives only  $\leq s$  rows per row, but the condition  $s \leq n^{1/2}$  allows us to lower bound as  $\Omega(1)$  the probability that an individual row of the random matrix  $A$  in [Raz16a, Appendix A] does not have collisions. Retaining only the rows without collision gives the slight modification we need here.

**Proof of Lemma 5.2.** We begin with the observation that was apparently first made by Babai and Seress in [BS92]: the symmetric group  $\text{Sym}(D)$  contains elements  $\sigma$  of exponential order. More specifically, let  $p_1 + \dots + p_n \leq |D| - 2 < p_1 + \dots + p_n + p_{n+1}$ , where  $p_1 < p_2 < \dots < p_n < \dots$  is the list of all prime numbers, take pairwise disjoint  $D_i \subseteq D$  with  $|D_i| = p_i$  ( $1 \leq i \leq n$ ), and let  $\sigma$  act cyclically on every  $D_i$  and identically on  $D \setminus (D_1 \cup \dots \cup D_n)$ . Let  $\tilde{P}$  be any transversal of the set  $\{D_1, \dots, D_n\}$ , then the orbit of  $\tilde{P}$  in the induced action of  $\sigma$  on  $\mathcal{P}(D)$  also has size  $\geq \exp(|D|^{\Omega(1)})$ , denote it by  $r$ ; all sets  $\tilde{P}, \sigma(\tilde{P}), \sigma^2(\tilde{P}), \dots, \sigma^{r-1}(\tilde{P})$  are pairwise distinct and  $\sigma^r(\tilde{P}) = \tilde{P}$ . Since all these sets  $\{\sigma^i(\tilde{P}) \mid 0 \leq i \leq r-1\}$  also have the same size, they are moreover independent w.r.t. inclusion. Let now  $P \stackrel{\text{def}}{=} \tilde{P} \cup \{a\}$ , where  $a \in D \setminus (D_1 \cup \dots \cup D_n)$  is an arbitrary fixed element. Then (since  $|D \setminus (D_1 \cup \dots \cup D_n)| \geq 2$ ) we additionally have that the  $(2r)$  sets

$$\left\{ \sigma^i(P) \mid 0 \leq i \leq r-1 \right\}, \left\{ D \setminus \sigma^i(P) \mid 0 \leq i \leq r-1 \right\} \quad (9)$$

are pairwise independent w.r.t. inclusion.

Let now  $X_0, X_1, X_2, X_3$  be  $D$ -valued variables. The required 2-CSP  $\eta$  has the following constraints, where  $Q \subseteq D$  is an arbitrary subset different from  $\emptyset$  and  $D$ :

$$\begin{aligned} X_0^Q & \\ X_0^Q & \rightarrow X_1^P \\ X_2 & = X_1 \\ X_3 & = X_2 \\ X_1 & = \sigma(X_3) \\ X_3^{\sigma^{r/2}(P)} & \rightarrow X_0^{D \setminus Q}. \end{aligned}$$

The refutation  $\pi$  from  $\eta$  with  $\text{VSpace}(\pi) = 1$  is straightforward:

$$1, X_0^Q, X_1^P, X_2^P, X_3^P, X_1^{\sigma(P)}, \dots, X_1^{\sigma^2(P)}, \dots, X_1^{\sigma^{r/2}(P)}, X_2^{\sigma^{r/2}(P)}, X_3^{\sigma^{r/2}(P)}, X_0^{D \setminus Q}, 0.$$

In order to prove the second statement in Lemma 5.2, we show that this refutation, its inverse and its contrapositive are essentially the only non-trivial inferences with variable space 1. More specifically, let

$$\begin{aligned} \mathcal{L}_t \stackrel{\text{def}}{=} \{X_0^Q\} \cup & \left\{ X_i^{\sigma^h(P)} \mid i \in [3], h \in \mathbb{Z}, |h| \leq t-2 \right\} \\ & \cup \left\{ X_i^{D \setminus \sigma^h(P)} \mid i \in [3], h \in \mathbb{Z}, |h-r/2| \leq t-2 \right\}, \end{aligned}$$

and let

$$\pi = 1, X_{i_1}^{A_1}, \dots, X_{i_t}^{A_t}, 0$$

be a semantical refutation of variable space 1. We claim that as long as  $t \leq r/2$ ,  $X_{i_t}^{A_t}$  is a weakening of a literal in  $\mathcal{L}_t$ .

**Inductive base**  $t = 1$  is obvious since  $X_0^Q$  is the only constraint in  $\eta$  of width 1.

**Inductive step.**

Let  $t \leq r/2$ . We have to prove that if  $X_i^A \in \mathcal{L}_t$ ,  $X_j^B$  is a generalized literal and

$$X_i^A \wedge \eta[\{X_i, X_j\}] \models X_j^B$$

then  $X_j^B$  is a weakening of a literal in  $\mathcal{L}_{t+1}$ . This is by a routine case analysis; the only case worth mentioning here is  $i \in \{1, 3\}$  and  $j = 0$ , this is where we need the assumption  $t \leq r/2$ . By symmetry, assume that  $i = 1$ , then  $\eta[\{X_0, X_1\}] \equiv X_0^Q \wedge X_1^P$ . But since  $X_i^A \in \mathcal{L}_t$  and  $t \leq r/2$ , we conclude that  $A \cap P \neq \emptyset$  since all sets in (9) are independent w.r.t. inclusion. Hence  $X_1^A \wedge \eta[\{X_0, X_1\}] \models X_0^B$  actually implies that  $B \supseteq Q$  and thus  $X_0^B$  is a weakening of  $X_0^Q$ . ■LEMMA 5.2

**Proof of Lemma 5.4.** Fix  $\eta_1, \dots, \eta_h$  as in the statement, and let  $\eta \stackrel{\text{def}}{=} \eta_h \cdot \dots \cdot \eta_1$  be their lexicographic product. Let us first verify that  $\text{VSpace}(\eta \vdash 0) = 1$ .

For every  $d \in [h]$  fix a refutation

$$\pi_d = 1, X_{i(d,1)}^{A(d,1)}, \dots, X_{i(d,T-1)}^{A(d,T-1)}, 0$$

of length  $T$ , where  $i(d,t) \in [\ell]$  and  $A(d,t) \subseteq D_d$ . For the uniformity of notation, we also let  $i(d,0) \stackrel{\text{def}}{=} i(d,1)$ ,  $A(d,0) \stackrel{\text{def}}{=} D_d$  and, likewise,  $i(d,T_d) \stackrel{\text{def}}{=} i(d,T_d - 1)$ ,  $A(d,T_d) \stackrel{\text{def}}{=} \emptyset$ . Denote by  $L(d,t) \stackrel{\text{def}}{=} X_{i(d,t)}^{A(d,t)}$  ( $t = 0..T$ ) the corresponding generalized literal.

For  $\vec{t} = (t_h, \dots, t_{h-1}, \dots, t_1) \in [0..T]^h$ , let  $v(\vec{t}) \stackrel{\text{def}}{=} (i(h, t_h), i(h-1, t_{h-1}), \dots, i(1, t_1)) \in V$  (this is a good place to recall that we enumerate everything from the leaves to the root!) and  $L(\vec{t}) \stackrel{\text{def}}{=} X_{v(\vec{t})}^{A(h,t_h) \cup \dots \cup A(1,t_1)}$  be the corresponding generalized  $D$ -valued literal. We claim that the sequence of generalized literals  $L(\vec{t})$ , taken in the lexicographic order, makes a refutation of  $\eta$ .

Indeed,  $L(0,0, \dots, 0) = X_{v(0, \dots, 0)}^D \equiv 1$  and  $L(T, \dots, T) = X_{v(T, \dots, T)}^\emptyset \equiv 0$ , as required. Given  $\vec{t} \neq (T, \dots, T)$ , let  $d \in [h]$  be the smallest index such

that  $t_d \neq T$ , say  $t_d = s$ , so that the next term in the lexicographic order is  $\vec{t}' \stackrel{\text{def}}{=} (t_h, \dots, t_{d+1}, s+1, 0 \dots, 0)$ . We have  $L(\vec{t}) = X_{v(\vec{t})}^{B \cup A(d,s)}$  and  $L(\vec{t}') = X_{v(\vec{t}')}^{B \cup A(d,s+1) \cup D_{d-1} \cup \dots \cup D_1}$  for the same  $B \subseteq D_h \cup \dots \cup D_{d+1}$ .

From the refutation  $\pi_d$  we know that  $X_{i(d,s)}^{A(d,s)} \wedge \eta_d[\{X_{i(d,s)}, X_{i(d,s+1)}\}] \models X_{i(d,s+1)}^{A(d,s+1)}$  in the  $D_d$ -valued logic. Then  $\eta[\{X_{v(\vec{t})}, X_{v(\vec{t}')}\}]$  entails, due to the second group of axioms, that  $(X_{v(\vec{t})}^{D_d} \wedge X_{v(\vec{t}')}^{D_d}) \rightarrow \eta_d[X_{\vec{t}}, X_{\vec{t}'}]$ . Also, as long as  $v(\vec{t}) \neq v(\vec{t}')$ ,  $\eta[\{X_{v(\vec{t})}, X_{v(\vec{t}')}\}]$  also contains the first group of axioms  $\text{Con}_d(X_{v(\vec{t})}, X_{v(\vec{t}')})$ . The required implication

$$X_{v(\vec{t})}^{B \cup A(d,s)} \wedge \eta[\{X_{v(\vec{t})}, X_{v(\vec{t}')}\}] \models X_{v(\vec{t}')}^{B \cup A_{d,s+1} \cup D_{d-1} \cup \dots \cup D_1}$$

follows straightforwardly. This completes the proof of  $\mathbf{VSpace}(\tau \vdash 0) \leq 1$ .

Let us now turn to the lower bound. Our overall strategy is quite typical for space complexity: we define a collection of ‘‘admissible’’ configurations  $\mathbb{A}$  that is simple enough to be controlled and, on the other hand, everything that we can infer in small space can be majorated by an admissible configuration from  $\mathbb{A}$ . The only twist is that since we are proving a *length* lower bound, this construction must necessarily be dynamic as well and consist of an increasing sequence  $\mathbb{A}_0 \subseteq \mathbb{A}_1 \subseteq \dots \subseteq \mathbb{A}_s \subseteq \dots$ , where configurations in  $\mathbb{A}_s$  majorate everything that can be inferred in small space *and* length  $\leq s$ . We just saw a relatively simple implementation of this idea in the proof of Lemma 5.2.

Starting the formal argument, recall that we have a natural ultrametric  $\rho$  on the set of variables  $V$ , and that non-trivial balls in this metric are naturally identified with the set of non-root vertices in the underlying tree. Let  $r(\mathcal{B})$  denote the radius of a ball  $\mathcal{B}$ .

**Definition 5.9 (normal terms)** Let  $\mathcal{B}$  be a ball of radius  $r$ ,  $0 \leq r \leq h-1$ , and let  $A \subseteq D_{r+1}$  be such that  $A \neq \emptyset$  and, moreover,  $A \neq D_1$  if  $r = 0$ . Then we denote by  $t_{\mathcal{B},A}$  the following term:

$$t_{\mathcal{B},A} \stackrel{\text{def}}{=} \bigwedge_{v \in \mathcal{B}} X_v^{D_h \cup \dots \cup D_{r+2} \cup A}. \quad (10)$$

A term  $t$  is *normal* if it can be represented as

$$t = t_{\mathcal{B}_1, A_1} \wedge \dots \wedge t_{\mathcal{B}_w, A_w}, \quad (11)$$

where all balls are pairwise disjoint.

We remark that for any  $D$ -valued literal  $X_v^B$ , the set  $B$  *uniquely* determines the term  $t_{\mathcal{B},A}$  in which it may possibly appear. Hence the representation (11) of a normal term is unique and it what follows we will not distinguish between the two.

**Definition 5.10 (sparse terms)** Let us call two balls  $\mathcal{B}, \mathcal{B}'$  *adjacent* if they have the same radius  $r$  and  $\rho(\mathcal{B}, \mathcal{B}') = r + 1$ . A normal term (11) is *sparse* if no two balls  $\mathcal{B}_i, \mathcal{B}_j$  in it are adjacent.

**Definition 5.11 (complexity of normal terms)** Let a ball  $\mathcal{B}$  of radius  $r$  corresponds to a prefix  $(i_h, \dots, i_{r+1}) \in V^+$ ,  $i_\nu \in [\ell]$ . For  $A \subseteq D_{r+1}$ , let  $L(t_{\mathcal{B},A})$  be the minimal length of a space 1  $D_{r+1}$ -valued proof of the generalized literal  $X_{i_{r+1}}^A$  from  $\tau_{r+1}$ . For a normal term (11), we let  $L(t) \stackrel{\text{def}}{=} \max_{1 \leq i \leq w} L(t_{\mathcal{B}_i, A_i})$ .

Now we are ready to define the sets of admissible configurations  $\mathbb{A}_s$ .

**Definition 5.12 (admissible configurations)** For a term  $t$ , we let

$$t^* \stackrel{\text{def}}{=} t \wedge \eta[\text{Vars}(t)].$$

We let  $\mathbb{A}_s$  consist of all  $t^*$ , where  $t$  is a normal *sparse* term with  $L(t) \leq s$ .

Clearly,  $t^*$  is consistent for any normal  $t$  (assign all variables  $X_v$ ,  $v \in \mathcal{B}_i$  to an arbitrary fixed value  $a_i \in A_i$ ). Hence Lemma 5.4 readily follows from the following, which is the heart of our argument.

**Lemma 5.13** *Let  $1 = f_0, \dots, f_1 \dots, f_s$  be a  $D$ -valued semantical proof from  $\eta_h \cdot \eta_{h-1} \cdot \dots \cdot \eta_1$  of variable space  $\leq h/2 - 1$  with  $s \leq T - 1$ . Then there exists  $f \in \mathbb{A}_s$  such that  $f \models f_s$ .*

**Proof of Lemma 5.13.** By induction on  $s$ . The base case  $s = 0$  is obvious ( $1 = 1^* \in \mathbb{A}_0$ ).

For the inductive step, let  $t = t_{\mathcal{B}_1, A_1} \wedge \dots \wedge t_{\mathcal{B}_w, A_w}$  be a normal sparse term such that  $L(t) \leq s$ , where  $s \leq T - 2$ , with  $t^* \models f_s$ . Our goal is to construct a normal sparse term  $\hat{t}$  such that  $L(\hat{t}) \leq s + 1$  and  $\hat{t}^* \models f_{s+1}$ . This will complete the proof of Lemma 5.13.

Let<sup>8</sup>  $V_0 \stackrel{\text{def}}{=} \text{Vars}(f_s) \cup \text{Vars}(f_{s+1})$ ; note that  $|V_0| \leq 2(h/2 - 1) = h - 2$ . We have  $f_s \wedge \eta[V_0] \models f_{s+1}$ , and hence it is sufficient to construct a normal sparse term  $\hat{t}$  with  $L(\hat{t}) \leq s + 1$  satisfying

$$\hat{t}^* \models f_s \wedge \eta[V_0]. \quad (12)$$

**Definition 5.14** For a ball  $\mathcal{B}$  with  $r(\mathcal{B}) \leq h - 1$ ,  $\mathcal{B}^+$  is the uniquely defined ball of radius  $r(\mathcal{B}) + 1$  such that  $\mathcal{B}^+ \supset \mathcal{B}$ .

**Claim 5.15** *The set  $V_0$  can be covered by a collection of balls  $\{\mathcal{B}_1^*, \dots, \mathcal{B}_{w^*}^*\}$  of radii  $\leq h - 1$  each such that the balls  $(\mathcal{B}_1^*)^+, \dots, (\mathcal{B}_{w^*}^*)^+$  are pairwise disjoint.*

**Remark 2** Note that this property of  $\{\mathcal{B}_1^*, \dots, \mathcal{B}_{w^*}^*\}$  is much stronger than the sparsity required in Definition 5.10. Unfortunately, we can not maintain it inductively as it in general will be destroyed when merging the collection coming from Claim 5.15 and the one underlying the old term  $t$ , see (13) below for details.

**Proof of Claim 5.15.** Let us call a covering of the set  $V_0$  by pairwise disjoint balls *frugal* if every ball  $\mathcal{B}$  in this covering covers at least  $(r + 1)$  elements of  $V_0$ . Frugal coverings do exist: take, for example, the trivial covering by balls of radius 0. Now pick up a frugal covering with the smallest possible number of balls. We claim that it has all the required properties.

Indeed, the bound  $r(\mathcal{B}^*) \leq h - 1$  for a ball  $\mathcal{B}^*$  in our frugal covering simply follows from the definition of frugality and the bound  $|V_0| \leq h - 2$ . Next, if  $\mathcal{B}, \mathcal{B}'$  are two different balls in this coloring such that  $\mathcal{B}^+ \cap (\mathcal{B}')^+ \neq \emptyset$  then, by ultrametricity, one of these latter balls must contain another, say,  $\mathcal{B}^+ \supseteq (\mathcal{B}')^+ \supset \mathcal{B}'$ . Replacing  $\mathcal{B}$  with  $\mathcal{B}^+$  and removing all balls contained in  $\mathcal{B}^+$  (including  $\mathcal{B}'$ !), we will get a frugal covering with a smaller number of balls, a contradiction. Thus, all the balls in the minimal frugal covering are pairwise disjoint. ■<sub>CLAIM 5.15</sub>

The collection of disjoint balls from Claim 5.15 is not a priori anyhow related to the collection  $\{\mathcal{B}_1, \dots, \mathcal{B}_w\}$  underlying the normal sparse term  $t$ , and our next task is to relate the two. From now on, we fix a collection of balls  $\{\mathcal{B}_1^*, \dots, \mathcal{B}_{w^*}^*\}$  satisfying the conclusion of Claim 5.15.

---

<sup>8</sup>From this point on we freely identify sets of variables and their indices whenever it does not create confusion.

Let  $\Gamma_0 \subseteq [w]$  consist of those  $\gamma$  for which  $\mathcal{B}_\gamma$  is *properly* contained in a ball  $\mathcal{B}_\mu^*$  ( $\mu \in [w^*]$ ). Let  $M_0 \subseteq [w^*]$  be the set of all those  $\mu$  for which  $\mathcal{B}_\mu^*$  is contained (*not necessarily properly*) in one of the  $\mathcal{B}_\gamma$  ( $\gamma \in [w]$ ). By ultrametricity, all balls  $\{\mathcal{B}_\gamma \mid \gamma \notin \Gamma_0\}$ ,  $\{\mathcal{B}_\mu^* \mid \mu \notin M_0\}$  are pairwise disjoint. They still may contain adjacent balls, though.

Let  $\Gamma_1 \subseteq [w]$  be the set of all balls  $\mathcal{B}_\gamma$  such that  $\mathcal{B}_\gamma \subseteq (\mathcal{B}_\mu^*)^+ \setminus \mathcal{B}_\mu^*$  for at least one  $\mu \in [w^*]$ . Note that if  $\mathcal{B}_\gamma$  is adjacent to a ball  $\mathcal{B}_\mu^*$  then  $\gamma \in \Gamma_1$ . Also, since all  $(\mathcal{B}_\mu^*)^+$  ( $\mu \in [w^*]$ ) are pairwise disjoint, it follows that for any  $\gamma \in \Gamma_1$ ,  $\mathcal{B}_\gamma$  is disjoint with *all* balls  $\mathcal{B}_\mu^*$  ( $\mu \in [w^*]$ ), *including*  $\mu \in M_0$ . Hence, in particular,  $\Gamma_0 \cap \Gamma_1 = \emptyset$ . Moreover, the ball  $\mathcal{B}_\mu^*$  with  $\mathcal{B}_\nu \subseteq (\mathcal{B}_\mu^*)^+ \setminus \mathcal{B}_\mu^*$  is uniquely defined, and we let

$$\Gamma_1^\mu \stackrel{\text{def}}{=} \left\{ \gamma \mid \mathcal{B}_\gamma \subseteq (\mathcal{B}_\mu^*)^+ \setminus \mathcal{B}_\mu^* \right\};$$

thus,  $\Gamma_1 = \dot{\bigcup}_{\mu \in [w^*]} \Gamma_1^\mu$ . A word of warning:  $\Gamma_1^\mu$  may be non-empty even if  $\mu \in M_0$  (more precisely, when  $\mathcal{B}_\mu^* = \mathcal{B}_{\gamma'}$  for some  $\gamma' \in [w]$ , see Claim 5.16 below).

Now, the balls  $\{\mathcal{B}_\gamma \mid \gamma \notin \Gamma_0 \cup \Gamma_1\}$ ,  $\{\mathcal{B}_\mu^* \mid \mu \notin M_0\}$  are not only pairwise disjoint but also pairwise non-adjacent. They will make the support of the sparse term  $\hat{t}$  we are constructing, that is

$$\hat{t} = \bigwedge_{\gamma \notin \Gamma_0 \cup \Gamma_1} t_{\mathcal{B}_\gamma, A_\gamma} \wedge \bigwedge_{\mu \notin M_0} t_{\mathcal{B}_\mu^*, A_\mu^*}, \quad (13)$$

where for  $\mu \notin M_0$  the sets  $A_\mu^*$  are defined as follows. Let  $\mu \notin M_0$  and  $r \stackrel{\text{def}}{=} r(\mathcal{B}_\mu^*)$ .

**Case 1.**  $r(\mathcal{B}_\gamma) < r$  for any  $\gamma \in \Gamma_1^\mu$  (which in particular includes the case  $\Gamma_1^\mu = \emptyset$ ).

We simply let  $A_\mu^* \stackrel{\text{def}}{=} D_{r+1}$  unless  $r = 0$  in which case, due to our convention, we simply remove  $t_{\mathcal{B}_\mu^*, A_\mu^*}$  from (13).

**Case 2.** There exists  $\gamma \in \Gamma_1^\mu$  with  $r(\mathcal{B}_\gamma) = r$ .

First note that  $\gamma$  with this property is unique since  $t$  is sparse.  $\mathcal{B}_\gamma$  and  $\mathcal{B}_\mu^*$  are defined by two prefixes of the form  $(i_h, i_{h-1}, \dots, i_{r+2}, i)$  and  $(i_h, i_{h-1}, \dots, i_{r+2}, j)$  with  $i \neq j$ . We let  $A_\mu^*$  be the *minimal* subset of  $D_{r+1}$  for which

$$X_i^{A_\gamma} \wedge \eta[X_i, X_j] \models X_j^{A_\mu^*} \quad (14)$$

in the  $D_{r+1}$ -valued logic. We note that  $L(t_{\mathcal{B}_\mu, A_\mu^*}) \leq s + 1$  and hence (this is quite essential for the upcoming argument!)  $A_\mu^* \neq \emptyset$  due to the assumption  $s \leq T - 2$ .

This completes the construction of the sparse term  $\hat{t}$ , and all that remains is to prove (12).

**Claim 5.16** *If  $\Gamma_1^\mu \neq \emptyset$  then  $\hat{t}$  contains a sub-term of the form  $t_{\mathcal{B}_\mu^*, A}$  for some  $A$ .*

**Proof of Claim 5.16.** If  $\mu \notin M_0$ , this is obvious. If  $\mu \in M_0$  then  $\mathcal{B}_\mu^* \subseteq \mathcal{B}_\gamma$  for some  $\gamma$  and there is another  $\gamma'$  with  $\mathcal{B}_{\gamma'} \subseteq (\mathcal{B}_\mu^*)^+ \setminus \mathcal{B}_\mu^*$ . We necessarily must have  $\mathcal{B}_\mu^* = \mathcal{B}_\gamma$  (otherwise,  $\mathcal{B}_{\gamma'} \subseteq \mathcal{B}_\gamma$ ). Clearly,  $\gamma \notin \Gamma_0 \cup \Gamma_1$  and hence  $t_{\mathcal{B}_\gamma, A_\gamma} = t_{\mathcal{B}_\mu^*, A_\gamma}$  appears in  $\hat{t}$ .  $\blacksquare_{\text{CLAIM 5.16}}$

**Claim 5.17**  $V_0 \subseteq \text{Varst}(\hat{t})$ .

**Proof of Claim 5.17.** Every  $v \in V_0$  is contained in one of the balls  $\mathcal{B}_\mu^*$ . If  $\mu \notin M_0$ , we are done, otherwise there exists  $\gamma \in [w]$  with  $\mathcal{B}_\mu^* \subseteq \mathcal{B}_\gamma$ . Like in the proof of Claim 5.16,  $\gamma \notin \Gamma_0 \cup \Gamma_1$ , hence  $t_{\mathcal{B}_\gamma, A_\gamma}$  appears in  $\hat{t}$  and thus  $v \in \text{Vars}(\hat{t})$ .  $\blacksquare_{\text{CLAIM 5.17}}$

As an immediate consequence, the second part of the implication in (12) is automatic, and we only have to prove that  $\hat{t}^* \models f_s$ .

**Claim 5.18** *Let  $\alpha$  be an arbitrary assignment satisfying a term  $t_{\mathcal{B}, A}$  of the form (10). Then  $\alpha$  satisfies all axioms  $\text{Con}_{\rho(u,v)}(x_u, x_v)$  ( $u, v \in \mathcal{B}$ ) if and only if  $\alpha$  is constant on  $\mathcal{B}$ .*

**Proof of Claim 5.18.** By an easy inspection.  $\blacksquare_{\text{CLAIM 5.18}}$

Let now  $\alpha \in V^D$  be an assignment satisfying  $\hat{t}^*$ . Comparing with the inductive assumption  $t^* \models f_s$  and noticing that  $\text{Vars}(f_s) \subseteq V_0$ , in order to prove that  $f_s(\alpha) = 1$ , we only have to show how to modify  $\alpha$  to another assignment  $\beta$  such that:

1.  $\alpha$  and  $\beta$  agree on  $V_0$ ;
2.  $t^*(\beta) = 1$ .

This  $\beta$  will be obtained from  $\alpha$  by re-defining the latter on the balls  $\{\mathcal{B}_\gamma \mid \gamma \in \Gamma_1\}$ . Consider an individual  $\mathcal{B}_\gamma$ ,  $\gamma \in \Gamma_1^\mu$  and let  $r \stackrel{\text{def}}{=} r(\mathcal{B}_\mu^*)$ . By Claim 5.16,  $\mathcal{B}_\mu^* \subseteq \text{Vars}(\hat{t})$ , and then by Claim 5.18 (since  $\alpha$  satisfies  $\eta[\mathcal{B}_\mu^*]$ ),  $\alpha|_{\mathcal{B}_\mu^*}$  is a constant  $a$  with  $a \in D_h \cup \dots \cup D_{r+2} \cup A_\mu^*$ .

**Case 1.**  $a \in D_h \cup \dots \cup D_{r+2}$ .

We simply let  $\beta|_{\mathcal{B}_\gamma} \equiv a$ .

**Case 2.1.**  $a \in A_\mu^*$  and  $r(\mathcal{B}_\gamma) = r$ , i.e.,  $\mathcal{B}_\gamma$  and  $\mathcal{B}_\mu^*$  are adjacent.

In the notation of (14), there exists  $b \in A_\gamma$  such that  $\eta[\{X_i, X_j\}](b, a) = 1$ ; otherwise  $a$  could have been removed from  $A_\mu^*$  in violation of the minimality of (14). Pick arbitrarily any such  $b$  and define  $\beta|_{\mathcal{B}_\gamma} \equiv b$ .

**Case 2.2.**  $a \in A_\mu^*$ ,  $r(\mathcal{B}_\gamma) < r$ .

We let  $\beta|_{\mathcal{B}_\gamma} \equiv b$ , where  $b \in D_{r(\mathcal{B}_\gamma)+1}$  is chosen in such a way that  $\eta[\{X_i\}](b) = 1$ . Here, as before,  $i$  is the last entry in the prefix describing the ball  $\mathcal{B}_\gamma$ .

The construction of  $\beta$  is complete.

**Claim 5.19**  $\alpha$  and  $\beta$  agree on all balls  $\mathcal{B}_\mu^*$  and on all balls  $\mathcal{B}_\gamma$  ( $\gamma \notin \Gamma_1$ ).

**Proof of Claim 5.19.** Follows from the above remarks that the balls  $\mathcal{B}_\gamma$  ( $\gamma \in \Gamma_1$ ) are disjoint from anything else.  $\blacksquare_{\text{CLAIM 5.19}}$

In particular,  $\alpha$  and  $\beta$  agree on  $V_0$ , and it remains to show that  $t^*(\beta) = 1$ . This requires a bit of case analysis.

First we check that  $t(\beta) = 1$ , that is  $t_{\mathcal{B}_\gamma, A_\gamma}(\beta) = 1$  for any  $\gamma \in [w]$ .

**Case 1.**  $\gamma \in \Gamma_0$ .

We have  $\mathcal{B}_\gamma \subset \mathcal{B}_\mu^*$  for some  $\mu \notin M_0$ , and by Claim 5.19,  $\alpha$  and  $\beta$  coincide on  $\mathcal{B}_\mu^*$ . Since  $r(\mathcal{B}_\gamma) \leq r(\mathcal{B}_\mu^*) - 1$ , we have  $t_{\mathcal{B}_\mu^*, A_\mu^*} \models t_{\mathcal{B}_\gamma, A_\gamma}$  regardless of the particular value of  $A_\mu^*$  (over which we do not have any control). But  $t_{\mathcal{B}_\mu^*, A_\mu^*}$  appears in  $\hat{t}$  and hence  $t_{\mathcal{B}_\mu^*, A_\mu^*}(\alpha) = 1$ .  $t_{\mathcal{B}_\gamma, A_\gamma}(\beta) = 1$  follows.

**Case 2.**  $\gamma \in \Gamma_1$ .

In this case  $t_{\mathcal{B}_\gamma, A_\gamma}(\beta) = 1$  directly follows from the way the assignment  $\beta$  was constructed.

**Case 3.**  $\gamma \notin \Gamma_0 \cup \Gamma_1$ .

Once again,  $\alpha$  and  $\beta$  coincide on  $\mathcal{B}_\gamma$ , and  $t_{\mathcal{B}_\gamma, A_\gamma}$  also appears in  $\hat{t}$ . Hence  $t_{\mathcal{B}_\gamma, A_\gamma}(\beta) = 1$ .

So far we have proved  $t(\beta) = 1$ , and what still remains is to show that  $\eta[Vars(t)](\beta) = 1$ . Let us fix  $C \in \eta$  with  $Vars(C) \subseteq Vars(t)$ . We need to prove that

$$C(\beta) = 1. \quad (15)$$

**Case 1.**  $Vars(C) \subseteq \mathcal{B}_\gamma$  for some  $\gamma$ .

Let  $r \stackrel{\text{def}}{=} r(\mathcal{B}_\gamma)$ .

**Case 1.1.**  $C = \widehat{C}_0(X_u, X_v)$  ( $u, v \in \mathcal{B}_\gamma$ ), where  $C_0 \in \eta_d$ ,  $d \stackrel{\text{def}}{=} \rho(u, v)$ .

This case is immediate from the already established fact  $t(\beta) = 1$  since it implies  $\beta_u, \beta_v \in D_h \cup \dots \cup D_{r+1}$ , while  $d \leq r$ .

**Case 1.2.**  $C = \text{Con}_{\rho(u,v)}(X_u, X_v)$ .

For every ball  $\mathcal{B}$  occurring in the right-hand side of (13),  $\alpha|_{\mathcal{B}}$  is constant by Claim 5.18 since  $\alpha$  satisfies all consistency axioms  $\text{Con}_{\rho(u,v)}(X_u, X_v)$  with  $u, v \in \mathcal{B} \subseteq Vars(\hat{t})$ . Following the same reasoning as in the proof of  $t(\beta) = 1$  above,  $\beta|_{\mathcal{B}_\gamma}$  is also a constant hence  $C(\beta) = 1$  by Claim 5.18.

So far we have treated axioms  $C$  of width 2 with  $Vars(C) \subseteq \mathcal{B}_\gamma$ . We divide the analysis of the case when  $C$  is of width 1 into two subcases, according to whether  $\gamma \in \Gamma_1$  or not.

**Case 1.3.**  $C = \widehat{C}_0(X_u)$ , where  $C_0 \in \tau_d$  for some  $d$  and  $\gamma \notin \Gamma_1$ .

Since  $X_u \in Vars(\hat{t})$ ,  $C(\alpha_u) = 1$ , and since  $\gamma \notin \Gamma_1$ ,  $C(\beta_u) = C(\alpha_u)$ . This gives (15).

**Case 1.4.**  $C = \widehat{C}_0(X_u)$ , where, as before,  $C_0 \in \tau_d$  for some  $d$  but  $\gamma \in \Gamma_1$ .

Let  $\gamma \in \Gamma_1^\mu$  and  $R \stackrel{\text{def}}{=} r(\mathcal{B}_\mu^*) \geq r$ . From our construction, either  $\alpha|_{\mathcal{B}_\mu^*} \in D_h \cup \dots \cup D_{R+2}$  and  $\beta|_{\mathcal{B}_\gamma} \equiv \alpha|_{\mathcal{B}_\mu^*}$ , or  $b \in D_{r+1}$  and  $\eta[X_i](b) = 1$ , where  $i$  is again the last entry in the prefix describing  $\mathcal{B}_\gamma$ .

**Case 1.4.1.**  $\beta|_{\mathcal{B}_\gamma} \equiv \alpha|_{\mathcal{B}_\mu^*} \in D_h \cup \dots \cup D_{R+2}$  ( $= a$ ).

We may assume  $d \geq R + 2$  as otherwise the statement is trivial. Pick arbitrarily  $u^* \in \mathcal{B}_\mu^*$ , then  $\rho(u, u^*) = R + 1$ . Hence  $u$  and  $u^*$  share the prefix of length  $h - d \leq h - R - 2$ , that is  $\widehat{C}_0(X_{u^*})$  is also in  $\eta$ . Now  $\widehat{C}_0(a) = 1$  follows from  $X_{u^*} \in Vars(\hat{t})$ .

**Case 1.4.2.**  $b \in D_{r+1}$  and  $\eta[i](b) = 1$ .

Again, this is obvious if  $d \neq r + 1$  and follows from  $C_0 \in \eta_d[\{i\}]$  otherwise.

We have completed the analysis of the case  $\text{Vars}(C) \subseteq \mathcal{B}_\gamma$  for a single ball  $\mathcal{B}_\gamma$ . In particular, we can and will now assume that the width of the constraint  $C$  is exactly 2:

**Case 2.**  $\text{Vars}(C) = \{u, v\}$ ,  $u \in \mathcal{B}_\gamma$  and  $v \in \mathcal{B}_{\gamma'}$  with  $\gamma \neq \gamma'$ .

Let  $d \stackrel{\text{def}}{=} \rho(u, v)$ ,  $r \stackrel{\text{def}}{=} r(\mathcal{B}_\gamma)$ ,  $r' \stackrel{\text{def}}{=} r(\mathcal{B}_{\gamma'})$ , so that  $r, r' \leq d - 1$  and, moreover, at least one of this inequalities is strict (since the balls  $\mathcal{B}_\gamma$ ,  $\mathcal{B}_{\gamma'}$  are non-adjacent).

**Case 2.1.**  $\gamma \notin \Gamma_1$  and  $\gamma' \notin \Gamma_1$ .

This case is immediate:  $\beta_u = \alpha_u$ ,  $\beta_v = \alpha_v$  and (15) simply follows from the fact that  $\alpha$  satisfies  $\eta[\text{Vars}(\hat{t})]$ .

**Case 2.2.**  $\gamma \in \Gamma_1$ .

Let  $\gamma \in \Gamma_1^\mu$  and  $R \stackrel{\text{def}}{=} (R_\mu^*)$  so that  $R \geq r$ . Let also  $a \stackrel{\text{def}}{=} \alpha|_{\mathcal{B}_\mu^*}$ ;  $a \in D_h \cup \dots \cup D_{R+1}$ .

The rest of the analysis splits into two rather different cases according to whether  $v \in (\mathcal{B}_\mu^*)^+$  or not.

**Case 2.2.1.**  $v \in (\mathcal{B}_\mu^*)^+$ , that is  $d \leq R + 1$ .

**Case 2.2.1.1.**  $a \in D_h \cup \dots \cup D_{R+2}$ .

According to the construction,  $\beta_u = \beta_v = a$ .  $\text{Con}_d(\beta_u, \beta_v) = 1$  follows immediately, and for  $\hat{C}_0(\beta_u, \beta_v)$  ( $C_0 \in \tau_d$ ) we only have to remark that  $a \notin D_d$  since  $d \leq R + 1$ .

**Case 2.2.1.2.**  $a \in D_{R+1}$ .

**Case 2.2.1.2.1.**  $v \in \mathcal{B}_\mu^*$ .

From our construction,  $d = R + 1$ ,  $\beta_v = a$ , and  $\beta_u \in D_{r+1}$ . Thus,  $\beta_u, \beta_v \in D_d \cup \dots \cup D_1$ , and this proves  $\text{Con}_d(\beta_u, \beta_v) = 1$ , as well as  $\hat{C}_0(\beta_u, \beta_v) = 1$  unless  $r = R$ , that is the balls  $\mathcal{B}_\gamma$  and  $\mathcal{B}_\mu^*$  are adjacent. In this latter case  $\hat{C}_0(\beta_u, a) = 1$  is guaranteed by our choice of  $\beta_u$ .

**Case 2.2.1.2.2.**  $v \in (\mathcal{B}_\mu^*)^+ \setminus \mathcal{B}_\mu^*$ . In this case  $\gamma' \in \Gamma_1^\mu$  as well, and, according to our construction,  $\beta_u \in D_{r+1}$  and  $\beta_v \in D_{r'+1}$ . Recalling that  $r+1, r'+1 \leq d$  and, moreover, at least one of the inequalities here is strict, both  $\text{Con}_d(\beta_u, \beta_v)$  and  $\hat{C}_0(\beta_u, \beta_v)$  ( $C_0 \in \tau_d$ ) are satisfied for trivial reasons.

At this moment, we are done with the case  $v \in (\mathcal{B}_\mu^*)^+$ .

**Case 2.2.2.**  $v \notin (\mathcal{B}_\mu^*)^+$  or, in other words,  $d \geq R + 2$ .

Pick arbitrarily  $u^* \in \mathcal{B}_\mu^*$ . Since  $\rho(u, u^*) = R + 1$ , by the ultrametric triangle inequality we get  $\rho(u^*, v) = d$ . In particular,  $C(X_{u^*}, X_v)$  is also an axiom of  $\eta$ .

**Claim 5.20**  $C(\beta_u, \beta_v) = C(\alpha_{u^*}, \beta_v)$ .

**Proof of Claim 5.20.** Readily follows from the dichotomy  $\beta_u = \beta_{u^*} = \alpha_{u^*}$  or  $\beta_u, \alpha_{u^*} \in D_{R+1} \cup \dots \cup D_1 \subseteq D_{d-1} \cup \dots \cup D_1$ .  $\blacksquare_{\text{CLAIM 5.20}}$

Thus, if  $\gamma' \notin \Gamma_1$  then  $\{u^*, v\} \subseteq \text{Vars}(\hat{t})$ ,  $\beta_v = \alpha_v$  and we are done since  $\alpha$  satisfies  $\hat{t}^*$ . On the other hand, if  $\gamma' \in \Gamma_1^{\mu'}$  for some  $\mu' \neq \mu$  then  $u^* \notin (\mathcal{B}_{\mu'}^*)^+$ , and we simply apply Claim 5.20 once more, this time with  $u = v$ ,  $v = u^*$ ,  $u^* = v^*$ , where  $v^* \in \mathcal{B}_{\mu'}^*$ .

This finally completes our case analysis. To re-cap the overall argument, we have proved (15) for any axiom  $C \in \eta$  with  $\text{Vars}(C) \subseteq \text{Vars}(t)$ . That is, for any assignment  $\alpha \in D^V$  with  $\hat{t}^*(\alpha) = 1$  we were able to modify it to some  $\beta \in V^D$  so that  $\alpha$  and  $\beta$  agree on  $V_0$  and  $t^*(\beta) = 1$ . This implies (12) and completes the inductive step.  $\blacksquare_{\text{LEMMA 5.13}}$

As we observed above, the lower bound in Lemma 5.4 follows immediately.  $\blacksquare_{\text{LEMMA 5.4}}$

**Proof of Lemma 5.8.** In the notation of this lemma, fix a semantical (Boolean) refutation  $\pi = (f_0, \dots, f_T)$  from  $\eta[g, A]$  with  $\text{VSpace}(\pi) \leq (hs)/16$ . In order to convert  $\pi$  to a  $D$ -valued refutation, we need to recall a few rudimentary facts about expanders.

**Definition 5.21** For a set of columns  $J \subseteq [n]$ , let

$$\text{Ker}(J) \stackrel{\text{def}}{=} \{i \in [m] \mid J_i(A) \subseteq J\}$$

be the set of rows completely contained in  $J$ . Let  $A \setminus J$  be the sub-matrix of  $A$  obtained by removing all columns in  $J$  and all rows in  $\text{Ker}(J)$ .

The following is a part of [Raz16a, Lemma 4.4].

**Proposition 5.22** *Let  $A$  be an  $(m \times n)$   $(r, c)$ -boundary expander in which every row has at most  $s$  ones, let  $c' < c$ , and let  $J \subseteq [n]$  satisfy  $|J| \leq \frac{r}{2}(c - c')$ . Then there exists  $\hat{J} \supseteq J$  such that  $A \setminus \hat{J}$  is an  $(r/2, c')$ -boundary expander and  $|\hat{J}| \leq |J| \left(1 + \frac{s}{c - c'}\right)$ .*

We now return to the proof of Lemma 5.8. Let<sup>9</sup>  $J_t \stackrel{\text{def}}{=} \text{Vars}(f_t)$ ;  $|J_t| \leq (hs)/16$ . Apply to this set Proposition 5.22 with  $r = 2h$ ,  $c = 3s/4$  and

<sup>9</sup>Recall that we often identify sets of variables with sets of their indices.

$c' = 5s/8$ . We will get  $\widehat{J}_t \supseteq J_t$  such that  $A \setminus \widehat{J}_t$  is an  $(h, 5s/8)$ -boundary expander and  $|\widehat{J}_t| \leq 9|J_t| \leq 9hs/16$ . Let  $I_t \stackrel{\text{def}}{=} \text{Ker}(\widehat{J}_t)$ ; we claim that  $|I_t| \leq h$ . Indeed, assuming the contrary, pick a set  $I'_t \subseteq I_t$  with  $|I'_t| = h$ . Then  $|\partial_A(I'_t)| \leq |\widehat{J}_t| \leq 9hs/16$ , contrary to the fact that  $A$  is an  $(h, 3s/4)$ -boundary expander.

We now let  $\widehat{f}_t$  be the *minimal*  $D$ -valued function in the variables  $\{y_i \mid i \in I_t\}$  such that

$$f_t \models \widehat{f}_t[g, A] \quad (16)$$

in the Boolean logic. Then  $|\text{Vars}(\widehat{f}_t)| \leq s$  and all that remains to show is that  $(\widehat{f}_0, \widehat{f}_1, \dots, \widehat{f}_T)$  is indeed a  $D$ -valued semantic refutation, that is

$$\widehat{f}_t \wedge \eta[I_t \cup I_{t+1}] \models \widehat{f}_{t+1}, \quad (17)$$

for all  $t$ .

Let  $\alpha \in D^m$  be any assignment satisfying the left-hand side in (17). Due to the minimality of  $\widehat{f}_t$ , if we re-define it to 0 on the input  $\alpha|_{I_t}$ , this will violate (16). In other words, there exists a Boolean assignment  $a \in \{0, 1\}^n$  such that  $f_t(a) = 1$  and

$$g(a|_{J_i(A)}) = \alpha_i, \quad (18)$$

for any  $i \in I_t$ . We note that these two properties of  $a$  depend only on those values  $a_j$  for which  $j \in \widehat{J}_t$ ; thus, we can view  $a$  as an assignment in  $\{0, 1\}^{\widehat{J}_t}$ , discarding all other values. Our goal is to extend  $a$  to an assignment in  $\{0, 1\}^{\widehat{J}_t \cup \widehat{J}_{t+1}}$  in such a way that (18) will be satisfied for all  $i \in I_{t+1}$  as well.

This is done by a fairly standard argument. Let  $I \stackrel{\text{def}}{=} I_{t+1} \setminus I_t$ . Since  $A \setminus \widehat{J}_t$  is an  $(h, 5s/8)$ -boundary expander and  $|I| \leq |I_{t+1}| \leq h$ , we have  $|\partial_A(I) \setminus \widehat{J}_t| \geq \frac{5s}{8}|I|$ . Hence for at least one  $i \in I$ ,

$$\left| J_i(A) \setminus \left( \widehat{J}_t \cup \bigcup_{i' \in I \setminus \{i\}} J_{i'}(A) \right) \right| \geq \frac{5s}{8} \geq \frac{s}{4}.$$

Removing this  $i$  from  $I$  and arguing by reverse induction, we can order all rows in  $I$  in such a way  $I = \{i_1, i_2, \dots, i_r\}$  that

$$\left| J_{i_\nu}(A) \setminus \left( \widehat{J}_t \cup J_{i_1}(A) \cup \dots \cup J_{i_{\nu-1}}(A) \right) \right| \geq \frac{s}{4} \quad (19)$$

for all  $\nu = 1..r$ . Using now  $(3s/4)$ -surjectivity of  $g$ , we consecutively extend  $a$  to  $\widehat{J}_t \cup J_{i_1}(A) \cup \dots \cup J_{i_\nu}(A)$  enforcing all conditions (18).

The partial assignment  $a \in \{0, 1\}^{\widehat{J}_t \cup \widehat{J}_{t+1}}$  we have constructed still satisfies  $f_t$ ; we claim that it also satisfies  $\eta[g, A] \left[ \widehat{J}_t \cup \widehat{J}_{t+1} \right] \supseteq \eta[g, A][J_t \cup J_{t+1}]$ .

Indeed, for any  $C \in \eta[I_t \cup I_{t+1}]$  this simply follows from the fact that  $C(\alpha) = 1$  and the consistency conditions (18). One thing we still have to make sure is that  $\eta[g, A] \left[ \widehat{J}_t \cup \widehat{J}_{t+1} \right]$  does not contain any other, “accidental” constraints.

**Claim 5.23** *If  $C$  is any constraint of width  $\leq h$  and  $\text{Vars}(C[g, A]) \subseteq \widehat{J}_t \cup \widehat{J}_{t+1}$  then  $\text{Vars}(C) \subseteq I_t \cup I_{t+1}$ .*

**Proof of Claim 5.23.** By a relatively simple modification of the argument above. Let  $I \stackrel{\text{def}}{=} \text{Vars}(C)$ ;  $|I| \leq h$ , and assume the contrary, that is that there exists  $i \in I \setminus (I_t \cup I_{t+1})$ . Fix two assignments  $\alpha, \beta \in D^I$  differing only in the  $i$ th coordinate but such that  $C(\alpha) \neq C(\beta)$ . We claim that there exist  $a, b \in \{0, 1\}^n$  such that (cf. (18))

$$g(a|_{J_i(A)}) = \alpha_i, \quad g(b|_{J_i(A)}) = \beta_i, \quad (20)$$

for all  $i \in I$  while  $a|_{\widehat{J}_t \cup \widehat{J}_{t+1}} = b|_{\widehat{J}_t \cup \widehat{J}_{t+1}}$ : the first property will imply  $C[g, A](a) \neq C[g, A](b)$ , and that will contradict  $\text{Vars}(C[g, A]) \subseteq \widehat{J}_t \cup \widehat{J}_{t+1}$  by the second property.

We construct the promised  $a, b$  in two stages. Let  $I' \stackrel{\text{def}}{=} I \cap (I_t \cup I_{t+1})$ ; thus,  $\alpha$  and  $\beta$  agree on  $I'$ . As before, order the rows in  $I'$  in such a way  $I' = \{I_1, \dots, I_r\}$  that

$$\left| J_{i_\nu}(A) \setminus (J_{i_1}(A) \cup \dots \cup J_{i_{\nu-1}}(A)) \right| \geq s/4$$

holds for all  $\nu$  (cf. (19)), and then satisfy (20) with the *same* assignment to  $J_{i_1}(A) \cup \dots \cup J_{i_r}(A)$ . Extend it to  $\widehat{J}_t \cup \widehat{J}_{t+1}$  arbitrarily; let  $c \in \{0, 1\}^{\widehat{J}_t \cup \widehat{J}_{t+1}}$  be the resulting assignment.

Now, let  $I'' \stackrel{\text{def}}{=} I \setminus (I_t \cup I_{t+1})$ , and let  $A^*$  be the matrix obtained from  $A$  by removing *all* columns  $J_t, J_{t+1}$  and all rows  $I_t, I_{t+1}$ . Since both  $A \setminus J_t$  and  $A \setminus J_{t+1}$  are  $(h/2, 5s/8)$ -expanders, clearly  $A^*$  is still an  $(h, s/4)$ -expander  $(\frac{s}{4} = 2 \cdot (\frac{5}{8}s) - s)$ . This expansion property allows us to extend  $c$ , by the same argument as above, to  $a, b \in \{0, 1\}^n$  that will satisfy (20) for  $i \in I''$  as well. But, as we remarked above, (20) is in contradiction with  $\text{Vars}(C[g, A]) \subseteq \widehat{J}_t \cup \widehat{J}_{t+1}$ . ■CLAIM 5.23

Since  $\eta$  is an  $h$ -CSP by the assumption of Lemma 5.8, we can apply Claim 5.23 to any  $C \in \eta$ . This gives us that all constraints in  $\eta[g, A] [\widehat{J}_t \cup \widehat{J}_{t+1}]$  are indeed coming from  $\eta[I_t \cup I_{t+1}]$ . As we already remarked above, this implies that all of them are satisfied by the assignment  $a$ , and since  $(f_0, f_1, \dots, f_T)$  is a semantical refutation from  $\tau[g, A]$ , we conclude that  $f_{t+1}(a) = 1$ . By (16),  $\widehat{f}_{t+1}[g, A] = 1$ , and since  $a$  satisfies (18) for all  $i \in I_{t+1}$ , this means  $\widehat{f}_{t+1}(\alpha) = 1$ .

We have established (17) by showing that any  $D$ -valued assignment  $\alpha$  satisfying its left-hand side also satisfies the right-hand side. Thus,  $(\widehat{f}_0, \widehat{f}_1, \dots, \widehat{f}_T)$  is indeed a semantical refutation.  $\blacksquare_{\text{LEMMA 5.8}}$

## 6. Very small space

In this section we prove Theorems 3.4 and 3.5.

**Proof of Theorem 3.4.** As we already remarked, this is a variation on the proof of Theorem 3.1 (the  $D(\tau \vdash 0) \leq 2\text{VSpace}^*(\tau \vdash 0)$  part), except that instead of binary search we now do  $T$ -ary search for a suitable  $T$ . But this time our goal is to come up with a configurational refutation rather than a tree-like one. Hence, an inductive description would be somewhat awkward, and we frame the argument as a direct construction instead.

Let  $\pi = (f_0, f_1, \dots, f_S)$  be a semantical refutation from  $\tau$  that has variable space  $\leq s$ . Assume w.l.o.g. that  $S$  is of the form  $(T+1)^h - 1$  for an integer  $T$ , and for  $t \in [0..S]$ , let  $(t_{h-1}, \dots, t_0)$  be its  $(T+1)$ -adic representation, that is  $t = \sum_{d=0}^{h-1} t_d(T+1)^d$ . For  $t > 0$ , let  $\text{ord}(t)$  be the minimal  $d$  for which  $t_d \neq 0$  (that is, the maximal  $d$  for which  $(T+1)^d | t$ ). Let  $t^{(k)}$  be the truncation of  $t$  by taking  $k$  most significant bits:  $t^{(k)} \stackrel{\text{def}}{=} \sum_{d=h-k}^{h-1} t_d(T+1)^d$ . In particular,  $t^{(0)} = 0$  and  $t^{(h)} = t$ . Let

$$\widehat{f}_t \stackrel{\text{def}}{=} (f_0 \rightarrow f_{t^{(1)}}) \wedge (f_{t^{(1)}} \rightarrow f_{t^{(2)}}) \wedge \dots \wedge (f_{t^{(h-1)}} \rightarrow f_t).$$

Clearly,  $|\text{Vars}(\widehat{f}_t)| \leq O(hs)$ .

Let us now take a look at  $\widehat{f}_{t+1}$ . Denoting  $k \stackrel{\text{def}}{=} h - \text{ord}(t+1)$ , we can remove from  $\widehat{f}_{t+1}$  all trivial terms  $f_{(t+1)^{(k)}} \rightarrow f_{(t+1)^{(k+1)}}, \dots, f_{(t+1)^{(h-1)}} \rightarrow f_{t+1}$  and write it down simply as

$$\widehat{f}_{t+1} \equiv (f_0 \rightarrow f_{t^{(1)}}) \wedge (f_{t^{(1)}} \rightarrow f_{t^{(2)}}) \wedge \dots \wedge (f_{t^{(k-2)}} \rightarrow f_{t^{(k-1)}}) \wedge (f_{t^{(k-1)}} \rightarrow f_{t+1}).$$

Hence  $\widehat{f}_t \wedge (f_t \rightarrow f_{t+1}) \models \widehat{f}_{t+1}$  and  $(\widehat{f}_0, \widehat{f}_1, \dots, \widehat{f}_s)$  is also a semantical refutation from  $\tau$  of the desired variable space  $O(hs)$ .

We convert it to a configurational resolution refutation as follows. First, for  $t \leq t'$  denote by  $\mathcal{C}(t, t')$  the straightforward CNF-expansion of  $f_t \rightarrow f_{t'}$ . Next, let  $\mathcal{C}_t \stackrel{\text{def}}{=} \mathcal{C}(0, t^{(1)}) \cup \mathcal{C}(t^{(1)}, t^{(2)}) \cup \dots \cup \mathcal{C}(t^{(h-1)}, t)$ ; this is our chosen CNF representation of the Boolean function  $\widehat{f}_t$ . Now the conversion is natural: to get from  $\mathcal{C}_t$  to  $\mathcal{C}_{t+1}$ , we first download all axioms in  $\tau[\text{Vars}(f_t) \cup \text{Vars}(f_{t+1})]$ , then write down the brute-force inference

$$\mathcal{C}(f_{t^{(k-1)}}, f_{t^{(k)}}), \dots, \mathcal{C}(f_{t^{(h-1)}}, f_t), \tau[\text{Vars}(f_t) \cup \text{Vars}(f_{t+1})] \vdash \mathcal{C}(f_{t^{(k-1)}}, f_{t+1}), \quad (21)$$

and, finally, erase all clauses in the left-hand side. It remains to bound the depth of this refutation (recall Definition 2.2).

Every individual step (21) has depth  $O(hs)$  as this is how many variables it involves. To get a bound on the depth of the tree formed by the inferences (21), we note that for every  $\mathcal{C}(f_a, f_b)$  in the left-hand side either  $\text{ord}(b) < \text{ord}(t+1) (= h-k)$ : this happens for all configurations but  $\mathcal{C}(f_{t^{(k-1)}}, f_{t^{(k)}})$ , or  $\text{ord}(b) = \text{ord}(t+1)$  and  $b < t+1$  ( $a = t^{(k-1)}$ ,  $b = t^{(k)}$ ,  $t_{h-k} \neq 0$ ), or it is trivial and can be removed ( $a = t^{(k-1)}$ ,  $b = t^{(k)}$ ,  $t_{h-k} = 0$ ). Hence the depth of the proof tree defined by the inferences (21) is  $O(hT)$ , and the required overall bound  $O(h^2sT)$  on depth follows.  $\blacksquare$ THEOREM 3.4

**Proof of Theorem 3.5.** Fix a configurational refutation  $\pi = (\mathcal{C}_0, \mathcal{C}_1, \dots, \mathcal{C}_T)$  from the Induction Principle  $\tau_n$  that has variable space  $s$ . Let us begin with a few generic remarks.

First, we can assume w.l.o.g. that for every  $0 \leq t \leq T-1$ ,  $\mathcal{C}_t$  does not contain the empty clause 0.

Next, let us call a clause *Bi-Horn* if it contains at most one occurrence of a positive literal and at most one occurrence of a negative literal. Since the set of bi-Horn clauses is closed under the Resolution rule, and all axioms in  $\tau_n$  are bi-Horn, all clauses appearing in our refutation must be also bi-Horn. In other words, for every  $t < T$ ,  $\mathcal{C}_t$  must entirely consist of literals and implications of the form  $x_i \rightarrow x_j$  ( $i \neq j$ ).

Next, for  $t \leq T-1$  we can remove from  $\mathcal{C}_t$  all clauses  $C$  with  $D_t(C) \geq D(\pi)$  and still get a configurational refutation (this reduction corresponds to removing non-essential clauses in [Ben09]). Hence, we can assume that

$$D_t(C) \leq D(\pi) - 1, \quad t \leq T-1, C \in \mathcal{C}_t. \quad (22)$$

Finally, we remark that Boolean restrictions naturally act on configurational refutations, and that under this action neither space nor depth may increase.

Let us now return to the proof of Theorem 3.5. The configuration  $\mathcal{C}_{T-1}$  must contain both literals  $x_i, \bar{x}_i$  of some variable  $i$ . Let  $r$  be the maximal index for which  $x_r$  appears in one of the clauses  $\mathcal{C}_0, \mathcal{C}_1, \dots, \mathcal{C}_{T-1}$ , and let  $\ell$  be the minimal index for which  $\bar{x}_\ell$  appears there. Note that  $\ell \leq i \leq r$ , and hence  $\text{Vars}(\mathcal{C}_{T-1})$  has a non-empty intersection with *both*  $\{x_0, \dots, x_r\}$  and  $\{x_\ell, x_{\ell+1}, \dots, x_n\}$ .

Choose  $a$  such that

$$\text{Vars}(\mathcal{C}_a) \cap \{x_0, x_1, \dots, x_r\} \neq \emptyset \wedge \text{Vars}(\mathcal{C}_a) \cap \{x_\ell, x_{\ell+1}, \dots, x_n\} \neq \emptyset$$

while for  $\mathcal{C}_{a-1}$  one of these properties is violated. By symmetry, we can assume w.l.o.g. that  $\text{Vars}(\mathcal{C}_{a-1}) \cap \{x_0, \dots, x_r\} = \emptyset$ .

Let us now apply to  $\pi$  the restriction  $\rho_+ : x_0 \rightarrow 1, x_1 \rightarrow 1, \dots, x_\ell \rightarrow 1$ . It transforms  $\tau_n$  to  $\tau_{n-\ell-1}$ , and since  $\bar{x}_\ell$  appears somewhere in the refutation (and is killed by  $\rho_+$ ), (22) implies that  $D(\pi|_{\rho_+}) \leq D(\pi) - 1$ .

Let us also apply to  $\pi$  the dual restriction  $\rho_- : x_\ell \rightarrow 0, x_{\ell+1} \rightarrow 0, \dots, x_n \rightarrow 0$ . Then  $\tau_n|_{\rho_-} = \tau_{\ell-1}$ . Next, every clause  $C$  in  $\mathcal{C}_{a-1}$  is a bi-Horn clause in the variables  $\{x_{r+1}, \dots, x_n\}$ , and, by the definition of  $r$ , it may not be a positive literal. Hence  $C$  must contain a negative literal which, since  $r \geq \ell$ , implies  $C|_{\rho_-} \equiv 1$ . Thus,  $\rho_-$  sets to 1 all clauses in  $\mathcal{C}_{a-1}$ , and since  $\text{Vars}(\mathcal{C}_b) \cap \{x_\ell, x_{\ell+1}, \dots, x_n\} \neq \emptyset$  for all  $b \geq a$ ,  $\rho_-$  reduces the *space* by at least one:  $\text{VSpace}(\pi|_{\rho_-}) \leq \text{VSpace}(\pi) - 1$ .

For the purpose of recursion, let  $D(n, s)$  be the minimum depth of a configurational refutation of  $\tau_{[n]}$  that has variable space  $\leq s$ . We have proved that

$$D(n, s) \geq \min_{0 \leq \ell \leq n} \{\max(D(n - \ell - 1, s) + 1, D(\ell - 1, s - 1))\}$$

which is bounded from below as  $\min \{D(n - n^{1-1/s} - 1, s) + 1, D(n^{1-1/s}, s - 1)\}$ .

This recurrence clearly resolves to  $D(n, s) \geq \Omega(n^{1/s})$ . ■THEOREM 3.5

## 7. Conclusion

In this paper we have studied two complexity measures of propositional proofs, variables space and depth, that in our view have been somewhat

neglected in the past. We hope that perhaps the nature of the results proved in this paper would help them to find the place in the overall hierarchy that, in our opinion, they fully deserve by the token of being very clean, robust and natural.

That said, the most interesting question about them remains open: whether variable space and depth are polynomially related or, equivalently, whether there exists a supercritical tradeoff between them. In a slightly less precise form this was asked by Urquhart [Urq11, Problem 7.2]; we have proved a quadratic gap, but the general problem looks quite challenging.

A positive answer to this question would immediately imply that clause space is polynomially bounded by variable space. Even if these two problems seem to be extremely tightly related, we still would like to ask this separately: is it correct that

$$\text{CSpace}(\tau_n \vdash 0) \leq (\text{VSpace}(\tau_n \vdash 0) \log n)^{O(1)}?$$

In the opposite range, of (barely) constant variable space, all refutations a priori have small length, and we have shown that the depth can be reduced to, say,  $n$  while keeping the variable space constant and length polynomial. We would like to take this opportunity and re-iterate an interesting question of (somewhat) similar flavor asked by Nordström [Nor13, Open Problem 16]. Assume that we have a configurational refutation of constant *clause* space. Is it always possible to reduce *length* to polynomial while keeping the clause space constant? As with our first question, this one also looks quite challenging.

Finally, there still remains a considerable amount of work to be done on refining simulations in Theorem 3.1. For example, it only implies that

$$\tilde{\Omega}(D^{1/2}) \leq \text{TSpace} \leq O(D^2), \tag{23}$$

and by Bonacina's result (4), every  $O(1)$ -CNF  $\tau_n$  with  $w(\tau_n \vdash 0) = \Theta(n)$  automatically provides an example with  $\text{TSpace}(\tau_n \vdash 0) = \Theta(D^2)$  ( $= \Theta(n^2)$ ). But what about the lower bound in (23)? Can, say,  $\text{TSpace}$  be sub-linear in depth or the bound can be improved to  $\tilde{\Omega}(D)$ ? This does not seem to easily follow from any known results.
