A Time-Space Lower Bound for a Large Class of Learning Problems

Ran Raz∗

Abstract

We prove a general time-space lower bound that applies for a large class of learning problems and shows that for every problem in that class, any learning algorithm requires either a memory of quadratic size or an exponential number of samples.

Our result is stated in terms of the norm of the matrix that corresponds to the learning problem. Let \( X, A \) be two finite sets. Let \( M : A \times X \to \{-1, 1\} \) be a matrix. The matrix \( M \) corresponds to the following learning problem: An unknown element \( x \in X \) was chosen uniformly at random. A learner tries to learn \( x \) from a stream of samples, \((a_1, b_1), (a_2, b_2), \ldots \), where for every \( i, a_i \in A \) is chosen uniformly at random and \( b_i = M(a_i, x) \).

Let \( \sigma_{\text{max}} \) be the largest singular value of \( M \) and note that always \( \sigma_{\text{max}} \leq |A|^{1/2} \cdot |X|^{1/2} \).

We show that if \( \sigma_{\text{max}} \leq |A|^{1/2} \cdot |X|^{1/2} - \varepsilon \), then any learning algorithm for the corresponding learning problem requires either a memory of size at least \( \Omega((\varepsilon n)^2) \) or at least \( 2^{\Omega(\varepsilon n)} \) samples, where \( n = \log_2 |X| \).

As a special case, this gives a new proof for the time-space lower bound for parity learning [R16].

1 Introduction

Several recent works studied the resources needed for learning, under memory constraints. The study was initiated by [S14, SVW16], followed by several additional works (see in particular [R16, VV16, KRT16, MM17]). While the main motivation for studying this problem comes from learning theory, the problem is also relevant to computational complexity and cryptography [R16, VV16, KRT16].

Steinhardt, Valiant and Wager conjectured that any algorithm for learning parities of size \( n \) requires either a memory of size \( \Omega(n^2) \) or an exponential number of samples. The conjecture was proven in [R16]. In particular, this shows for the first time a learning problem that is infeasible under super-linear memory constraints. Building on [R16], it was proved in [KRT16] that even if the parity is known to be of sparsity \( \ell \), parity learning remains infeasible under memory constraints that are super-linear in \( n \), as long as

∗Department of Computer Science, Princeton University. Research supported by the Simons Collaboration on Algorithms and Geometry. Email: ran.raz.mail@gmail.com
$\ell \geq \omega(\log n / \log \log n)$. Consequently, learning linear-size DNF Formulas, linear-size Decision Trees and logarithmic-size Juntas were all proved to be infeasible under super-linear memory constraints [KRT16].

The techniques presented in [R16, KRT16] are very specific for learning parities. (The results for learning DNF Formulas, Decision Trees and Juntas are proved by reductions from learning sparse parities). Indeed, the results in [R16, KRT16] are proved by first considering “linear” algorithms that are only allowed to store linear equations in their memory and the general case is proved by a reduction to the linear case.

Our Results

In this work, we present a new technique for proving infeasibility of learning under super-linear memory constraints. The technique seems very general. In particular, our main result applies for a large class of learning problems and shows that for every problem in that class, any learning algorithm requires either a memory of quadratic size or an exponential number of samples.

Let $X, A$ be two finite sets of size larger than 1 (where $X$ represents the concept-class that we are trying to learn and $A$ represents the set of possible samples).

Let $M : A \times X \rightarrow \{-1, 1\}$ be a matrix. The matrix $M$ represents the following learning problem: An unknown element $x \in X$ was chosen uniformly at random. A learner tries to learn $x$ from a stream of samples, $(a_1, b_1), (a_2, b_2), \ldots$, where for every $i$, $a_i \in A$ is chosen uniformly at random and $b_i = M(a_i, x)$.

Denote by $\sigma_{\max}(M)$ the largest singular value of $M$. Since the entries of $M$ are in $\{-1, 1\}$, it is always the case that

$$\sigma_{\max}(M) \leq |A|^{\frac{1}{2}} \cdot |X|^{\frac{1}{2}}.$$

Our main result, restated as Theorem 1, shows that if

$$\sigma_{\max}(M) \leq |A|^{\frac{1}{2}} \cdot |X|^{\frac{1}{2}} - \varepsilon$$

(where $\varepsilon > 0$ is not necessarily a constant), then any learning algorithm for the learning problem represented by $M$ requires either a memory of size at least $\Omega((\varepsilon n)^2)$ or at least $2^{\Omega(\varepsilon n)}$ samples, where $n = \log_2 |X|$.

For example, in the problem of parity learning, $|A| = |X| = 2^n$, and $M = H$ is Hadamard matrix. Hadamard matrix satisfies

$$\sigma_{\max}(H) = |A|^{\frac{1}{2}} \leq |A|^{\frac{1}{2}} \cdot |X|^{\frac{1}{2}} - \varepsilon,$$

where $\varepsilon = \frac{1}{2}$. Thus, as a special case of our main result, we obtain a new proof for the memory-samples lower bound for parity learning [R16] (with a completely different set of techniques and slightly better constants).

Related Work

Independently of our work, Moshkovitz and Moshkovitz have recently considered the graph that corresponds to a learning problem (which is similar to our matrix $M$, except that it is viewed as a bipartite graph with 1 representing an edge and $-1$ representing a none-edge).
They proved that if that graph has a (sufficiently strong) mixing property then any learning algorithm for the corresponding learning problem requires either a memory of size at least $1.25 \cdot n$ or at least $2^{\Omega(n)}$ samples [MM17].

2 Preliminaries

Denote by $U_X : X \to \mathbb{R}^+$ the uniform distribution over $X$.

For a random variable $Z$ and an event $E$, we denote by $\mathbb{P}_Z$ the distribution of the random variables $Z$, and we denote by $\mathbb{P}_{Z|E}$ the distribution of the random variable $Z$ conditioned on the event $E$.

Viewing a Learning Problem as a Matrix

Let $X$, $A$ be two finite sets of size larger than 1. Let $n = \log_2 |X|$.

Let $M : A \times X \to \{-1, 1\}$ be a matrix. The matrix $M$ corresponds to the following learning problem: There is an unknown element $x \in X$ that was chosen uniformly at random. A learner tries to learn $x$ from samples $(a, b)$, where $a \in A$ is chosen uniformly at random and $b = M(a, x)$. That is, the learning algorithm is given a stream of samples, $(a_1, b_1), (a_2, b_2)\ldots$, where each $a_t$ is uniformly distributed and for every $t$, $b_t = M(a_t, x)$.

Norms

For a function $f : X \to \mathbb{R}$, denote by $\|f\|_2$ the $\ell_2$ norm of $f$, with respect to the uniform distribution over $X$, that is:

$$\|f\|_2 = \left(\mathbb{E}_{x \in R^X} [f(x)^2]\right)^{1/2}.$$  

For a function $f : A \to \mathbb{R}$, denote by $\|f\|_2$ the $\ell_2$ norm of $f$, with respect to the uniform distribution over $A$, that is:

$$\|f\|_2 = \left(\mathbb{E}_{a \in R^A} [f(a)^2]\right)^{1/2}.$$  

The induced matrix norm on $M : A \times X \to \{-1, 1\}$ is defined by

$$\|M\|_2 = \sup_{f \neq 0} \frac{\|Mf\|_2}{\|f\|_2}.$$  

We note that

$$\|M\|_2 = \sqrt{\frac{|X|}{|A|}} \cdot \sigma_{\text{max}}(M),$$  

where $\sigma_{\text{max}}(M)$ denotes the largest singular value of $M$, and the factor $\sqrt{\frac{|X|}{|A|}}$ comes because in our definition of the $\ell_2$ norm of functions $f : X \to \mathbb{R}$ and $f : A \to \mathbb{R}$ we use expectation rather than (the more common) sum.

While $\|M\|_2$ and $\sigma_{\text{max}}(M)$ are equal, up to a normalization factor, it will be more convenient for us to work with $\|M\|_2$. 

3
Branching Program for a Learning Problem

In the following definition, we model the learner for the learning problem that corresponds to the matrix $M$, by a branching program.

**Definition 2.1. Branching Program for a Learning Problem:** A branching program of length $m$ and width $d$, for learning, is a directed (multi) graph with vertices arranged in $m+1$ layers containing at most $d$ vertices each. In the first layer, that we think of as layer 0, there is only one vertex, called the start vertex. A vertex of outdegree 0 is called a leaf. All vertices in the last layer are leaves (but there may be additional leaves). Every non-leaf vertex in the program has $2|A|$ outgoing edges, labeled by elements $(a, b) \in A \times \{-1, 1\}$, with exactly one edge labeled by each such $(a, b)$, and all these edges going into vertices in the next layer. Each leaf $v$ in the program is labeled by an element $\tilde{x}(v) \in X$, that we think of as the output of the program on that leaf.

**Computation-Path:** The samples $(a_1, b_1), \ldots, (a_m, b_m) \in A \times \{-1, 1\}$ that are given as input, define a computation-path in the branching program, by starting from the start vertex and following at step $t$ the edge labeled by $(a_t, b_t)$, until reaching a leaf. The program outputs the label $\tilde{x}(v)$ of the leaf $v$ reached by the computation-path.

**Success Probability:** The success probability of the program is the probability that $\tilde{x} = x$, where $\tilde{x}$ is the element that the program outputs, and the probability is over $x, a_1, \ldots, a_m$ (where $x$ is uniformly distributed over $X$ and $a_1, \ldots, a_m$ are uniformly distributed over $A$, and for every $t$, $b_t = M(a_t, x)$).

### 3 Overview of the Proof

Let $B$ be a branching program for the learning problem that corresponds to the matrix $M$. We define the truncated-path, $\mathcal{T}$, to be the same as the computation-path of $B$, except that it sometimes stops before reaching a leaf. Roughly speaking, $\mathcal{T}$ stops before reaching a leaf if certain “bad” events, that make the analysis difficult, occur. Nevertheless, we show that the probability that $\mathcal{T}$ stops before reaching a leaf is negligible, so we can think of $\mathcal{T}$ as almost identical to the computation-path.

For a vertex $v$ of $B$, we denote by $E_v$ the event that $\mathcal{T}$ reaches the vertex $v$. For simplicity, we denote by $\Pr(v) = \Pr(E_v)$ the probability for $E_v$ (where the probability is over $x, a_1, \ldots, a_m$), and we denote by $\mathbb{P}_{x|v} = \mathbb{P}_{x|E_v}$ the distribution of the random variable $x$ conditioned on the event $E_v$. Similarly, for an edge $e$ of the branching program $B$, let $E_e$ be the event that $\mathcal{T}$ traverses the edge $e$. Denote, $\Pr(e) = \Pr(E_e)$, and $\mathbb{P}_{x|e} = \mathbb{P}_{x|E_e}$.

A vertex $v$ of $B$ is called significant if $\|\mathbb{P}_{x|v}\|_2$ is non-negligible. Roughly speaking, this means that conditioning on the event that $\mathcal{T}$ reaches the vertex $v$, a non-negligible amount of information is known about $x$. In order to guess $x$ with a non-negligible success probability, $\mathcal{T}$ must reach a significant vertex. Lemma 4.1 shows that the probability that $\mathcal{T}$ reaches any significant vertex is negligible.

To prove Lemma 4.1, we show that for every fixed significant vertex $s$, the probability that $\mathcal{T}$ reaches $s$ is extremely small (smaller than one over the number of vertices in $B$). Hence, we can use a union bound to prove the lemma.
The proof that the probability that \( \mathcal{T} \) reaches \( s \) is extremely small is the main part of our proof. To that end, we introduce the following functions to measure the progress made by the branching program towards reaching \( s \).

Let \( L_i \) be the set of vertices \( v \) in layer-\( i \) of \( B \), such that \( \Pr(v) > 0 \). Let \( \Gamma_i \) be the set of edges \( e \) from layer-\( (i - 1) \) of \( B \) to layer-\( i \) of \( B \), such that \( \Pr(e) > 0 \). Let

\[
Z_i = \sum_{v \in L_i} \Pr(v) \cdot \langle P_x|v, P_x|s \rangle^n,
\]

\[
Z'_i = \sum_{e \in \Gamma_i} \Pr(e) \cdot \langle P_x|e, P_x|s \rangle^n,
\]

where \( \langle \cdot, \cdot \rangle \) denotes inner product. We think of \( Z_i, Z'_i \) as measuring the progress made by the branching program, towards reaching a state with distribution similar to \( P_x|s \).

We show that each \( Z_i \) may only be negligibly larger than \( Z_{i-1} \). Hence, \( Z_i \) is negligible for every \( i \). On the other hand, if \( s \) is in layer-\( i \) then \( Z_i \) is at least \( \Pr(s) \cdot \langle P_x|s, P_x|s \rangle^n \). Thus, \( \Pr(s) \cdot \langle P_x|s, P_x|s \rangle^n \) must be negligible. Since \( s \) is significant, \( \langle P_x|s, P_x|s \rangle \) is non-negligible and hence \( \Pr(s) \) must be negligible.

The proof that \( Z_i \) may only be negligibly larger than \( Z_{i-1} \) is done in two steps: Claim 4.12 shows by a simple convexity argument that \( Z_i \leq Z'_i \). The hard part, that is done in Claim 4.10 and Claim 4.11, is to prove that \( Z'_i \) may only be negligibly larger than \( Z_{i-1} \).

For this proof, we define for every vertex \( v \), the set of edges \( \Gamma_{\text{out}}(v) \) that are going out of \( v \), such that \( \Pr(e) > 0 \). Claim 4.10 shows that for every vertex \( v \),

\[
\sum_{e \in \Gamma_{\text{out}}(v)} \Pr(e) \cdot \langle P_x|e, P_x|s \rangle^n
\]

may only be negligibly higher than

\[
\Pr(v) \cdot \langle P_x|v, P_x|s \rangle^n.
\]

For the proof of Claim 4.10, which is the hardest proof in the paper, we consider the function \( P_x|v \cdot P_x|s \). We first show how to bound \( \| P_x|v \cdot P_x|s \|_2 \). We then consider two cases: If \( \| P_x|v \cdot P_x|s \|_1 \) is negligible, then \( \langle P_x|v, P_x|s \rangle^n \) is negligible and doesn’t contribute much, and we show that for every \( e \in \Gamma_{\text{out}}(v) \), \( \langle P_x|e, P_x|s \rangle^n \) is also negligible and doesn’t contribute much. If \( \| P_x|v \cdot P_x|s \|_1 \) is non-negligible, we use the bound on \( \| P_x|v \cdot P_x|s \|_2 \) and the bound on \( M\|_2 \) to show that for almost all edges \( e \in \Gamma_{\text{out}}(v) \), we have that \( \langle P_x|e, P_x|s \rangle^n \) is very close to \( \langle P_x|v, P_x|s \rangle^n \). Only an exponentially small fraction of edges are “bad” and give a significantly larger \( \langle P_x|e, P_x|s \rangle^n \).

The reason that in the definitions of \( Z_i \) and \( Z'_i \) we raised \( \langle P_x|v, P_x|s \rangle \) and \( \langle P_x|e, P_x|s \rangle \) to the power of \( n \) is that this is the largest power for which the contribution of the “bad” edges is still small (as their fraction is exponentially small).

This outline oversimplifies many details. Let us briefly mention two of them. First, it is not so easy to bound \( \| P_x|v \cdot P_x|s \|_2 \). We do that by bounding \( \| P_x|s \|_2 \) and \( \| P_x|v \|_\infty \). In order to bound \( \| P_x|s \|_2 \), we force \( \mathcal{T} \) to stop whenever it reaches a significant vertex (and thus we are able to bound \( \| P_x|e \|_2 \) for every vertex reached by \( \mathcal{T} \)). In order to bound \( \| P_x|v \|_\infty \), we force \( \mathcal{T} \) to stop whenever \( P_x|v(x) \) is large, which allows us to consider only the “bounded” part of \( P_x|v \). (This is related to the technique of flattening a distribution that was used.

5
in [KR13]). Second, some edges are so “bad” that their contribution to $Z_i'$ is huge so they cannot be ignored. We force $T$ to stop before traversing any such edge. (This is related to an idea that was used in [KRT16] of analyzing separately paths that traverse “bad” edges). We show that the total probability that $T$ stops before reaching a leaf is negligible.

4 Main Result

Theorem 1. Let $X, A$ be two finite sets. Let $n = \log_2 |X|$. Let $M : A \times X \to \{-1, 1\}$ be a matrix, such that $\|M\|_2 \leq 2^\gamma n$ (where $\gamma < 1$ is not necessarily a constant).

For any constant $\epsilon' < \frac{1}{3}$, there exists a (sufficiently small) constant $\epsilon' > 0$, such that the following holds: Let $c = \epsilon' \cdot (1 - \gamma)^2$, and let $\epsilon = \epsilon' \cdot (1 - \gamma)$. Let $B$ be a branching program of length at most $2^\epsilon n$ and width at most $2^{cn^2}$ for the learning problem that corresponds to the matrix $M$. Then, the success probability of $B$ is at most $O(2^{-\epsilon n})$.

Remark: We note that it is always the case that $\|M\|_2 \leq 2^n$, and that the condition $\|M\|_2 \leq 2^\gamma n$ is equivalent to $\sigma_{\text{max}}(M) \leq |A|^\frac{1}{2} \cdot |X|^\frac{1}{2} - \epsilon$, where $\epsilon = 1 - \gamma$.

Proof. Let $0 < \delta' < \frac{1}{3}$ and $0 < \beta' < 2$ be constants (to be optimized later on), such that, $\beta' + 6\delta' < 2$. Let $\epsilon' > 0$ be a sufficiently small constant (chosen to be sufficiently small after $\delta', \beta', \epsilon'$ were chosen). In particular, we will assume that $10\epsilon' < 2 - \beta' - 6\delta'$. Let $\delta = \delta' \cdot (1 - \gamma)$, $\beta = \beta' \cdot (1 - \gamma)$, $\epsilon = \epsilon' \cdot (1 - \gamma)$. Thus, $10\epsilon < 2 - \beta - 6\delta$.

Let $B$ be a branching program of length $m = 2^{\epsilon n}$ and width $d = 2^{cn^2}$ for the learning problem that corresponds to the matrix $M$. We will show that the success probability of $B$ is at most $O(2^{-\epsilon n})$. We will assume that $n$ is sufficiently large (chosen to be sufficiently large after $\delta', \beta', \epsilon'$ were chosen). This is justified because we only need to prove that the success probability of $B$ is at most $O(2^{-\epsilon n})$ (so $n$ can be assumed to be sufficiently large because of the big $O$).

4.1 The Truncated-Path and Additional Definitions and Notation

We will define the truncated-path, $T$, to be the same as the computation-path of $B$, except that it sometimes stops before reaching a leaf. Formally, we define $T$, together with several other definitions and notations, by induction on the layers of the branching program $B$.

Assume that we already defined the truncated-path $T$, until it reaches layer-$i$ of $B$. For a vertex $v$ in layer-$i$ of $B$, let $E_v$ be the event that $T$ reaches the vertex $v$. For simplicity, we denote by $\Pr(v) = \Pr(E_v)$ the probability for $E_v$ (where the probability is over $x, a_1, \ldots, a_m$), and we denote by $\mathbb{P}_{x|v} = \mathbb{P}_{x|E_v}$ the distribution of the random variable $x$ conditioned on the event $E_v$.

There will be three cases in which the truncated-path $T$ stops on a non-leaf $v$:
1. If \( v \) is a, so called, significant vertex, where the \( \ell_2 \) norm of \( \mathbb{P}_{x|v} \) is non-negligible. (Intuitively, this means that conditioned on the event that \( \mathcal{T} \) reaches \( v \), a non-negligible amount of information is known about \( x \)).

2. If \( \mathbb{P}_{x|v}(x) \) is non-negligible. (Intuitively, this means that conditioned on the event that \( \mathcal{T} \) reaches \( v \), the correct element \( x \) could have been guessed with a non-negligible probability).

3. If \( (M \cdot \mathbb{P}_{x|v})(a_{i+1}) \) is non-negligible. (Intuitively, this means that \( \mathcal{T} \) is about to traverse a “bad” edge, which is traversed with a non-negligibly higher or lower probability than other edges).

Next, we describe these three cases more formally.

**Significant Vertices**

We say that a vertex \( v \) in layer-\( i \) of \( B \) is **significant** if

\[
\| \mathbb{P}_{x|v} \|_2 > 2^{\delta n} \cdot 2^{-n}.
\]

**Significant Values**

Even if \( v \) is not significant, \( \mathbb{P}_{x|v} \) may have relatively large values. For a vertex \( v \) in layer-\( i \) of \( B \), denote by \( \text{Sig}(v) \) the set of all \( x' \in X \), such that,

\[
\mathbb{P}_{x|v}(x') > 2^{2(\delta + \epsilon - n)} \cdot 2^{-n}.
\]

**Bad Edges**

For a vertex \( v \) in layer-\( i \) of \( B \), denote by \( \text{Bad}(v) \) the set of all \( \alpha \in A \), such that,

\[
\left| (M \cdot \mathbb{P}_{x|v})(\alpha) \right| \geq 2^{(\delta + \gamma + \epsilon - n)} \cdot 2^{-n}.
\]

**The Truncated-Path \( \mathcal{T} \)**

We define \( \mathcal{T} \) by induction on the layers of the branching program \( B \). Assume that we already defined \( \mathcal{T} \) until it reaches a vertex \( v \) in layer-\( i \) of \( B \). The path \( \mathcal{T} \) stops on \( v \) if (at least) one of the following occurs:

1. \( v \) is significant.
2. \( x \in \text{Sig}(v) \).
3. \( a_{i+1} \in \text{Bad}(v) \).
4. \( v \) is a leaf.

Otherwise, \( \mathcal{T} \) proceeds by following the edge labeled by \( (a_{i+1}, b_{i+1}) \) (same as the computational-path).
4.2 Proof of Theorem 1

Since $\mathcal{T}$ follows the computation-path of $B$, except that it sometimes stops before reaching a leaf, the success probability of $B$ is bounded (from above) by the probability that $\mathcal{T}$ stops before reaching a leaf, plus the probability that $\mathcal{T}$ reaches a leaf $v$ and $\bar{x}(v) = x$.

The main lemma needed for the proof of Theorem 1 is Lemma 4.1 that shows that the probability that $\mathcal{T}$ reaches a significant vertex is at most $O(2^{-\epsilon n})$.

**Lemma 4.1.** The probability that $\mathcal{T}$ reaches a significant vertex is at most $O(2^{-\epsilon n})$.

Lemma 4.1 is proved in Section 4.3. We will now show how the proof of Theorem 1 follows from that lemma.

Claim 4.2. If $v$ is a non-significant vertex of $B$ then
\[ \Pr_x [x \in \text{Sig}(v) \mid E_v] \leq 2^{-2\epsilon n}. \]

**Proof.** Since $v$ is not significant,
\[ \mathbb{E}_{x' \sim \mathbb{P}_{x'|v}} [\mathbb{P}_{x'|v}(x')] = \sum_{x' \in \mathcal{X}} [\mathbb{P}_{x'|v}(x')]^2 = 2^n \cdot \mathbb{E}_{x' \sim \mathcal{X}} [\mathbb{P}_{x'|v}(x')]^2 \leq 2^{2\delta n} \cdot 2^{-n}. \]

Hence, by Markov’s inequality,
\[ \Pr_{x' \sim \mathbb{P}_{x'|v}} [\mathbb{P}_{x'|v}(x') > 2^{2\epsilon n} \cdot 2^{2\delta n} \cdot 2^{-n}] \leq 2^{-2\epsilon n}. \]

Since conditioned on $E_v$, the distribution of $x$ is $\mathbb{P}_{x|v}$, we obtain
\[ \Pr_x [x \in \text{Sig}(v) \mid E_v] = \Pr_x [\mathbb{P}_{x'|v}(x) > 2^{2\epsilon n} \cdot 2^{2\delta n} \cdot 2^{-n}) \mid E_v] \leq 2^{-2\epsilon n}. \]

Claim 4.3. If $v$ is a non-significant vertex of $B$ then
\[ \Pr_{a_{i+1}} [a_{i+1} \in \text{Bad}(v)] \leq 2^{-2\epsilon n}. \]

**Proof.** Since $v$ is not significant,
\[ \mathbb{E}_{\alpha \in \mathcal{R}} [(M \cdot \mathbb{P}_{x|v})(\alpha)]^2 = \|M \cdot \mathbb{P}_{x|v}\|^2 \leq \|M\|^2 \cdot \|\mathbb{P}_{x|v}\|^2 \leq 2^{2\gamma n} \cdot 2^{2\delta n} \cdot 2^{-2n}. \]

Hence, by Markov’s inequality,
\[ \Pr_{\alpha \in \mathcal{R}} [\alpha \in \text{Bad}(v)] = \Pr_{\alpha \in \mathcal{R}} [(M \cdot \mathbb{P}_{x|v})(\alpha) \geq 2^{(\delta+\gamma+\epsilon)n} \cdot 2^{-n}] \]
\[ = \Pr_{\alpha \in \mathcal{R}} [(M \cdot \mathbb{P}_{x|v})(\alpha)]^2 \geq 2^{2\epsilon n} \cdot 2^{2\gamma n} \cdot 2^{2\delta n} \cdot 2^{-2n} \leq 2^{-2\epsilon n}. \]

The claim follows since $a_{i+1}$ is uniformly distributed over $A$. 

8
We can now use Lemma 4.1, Claim 4.2 and Claim 4.3 to prove that the probability that \( \mathcal{T} \) stops before reaching a leaf is at most \( O(2^{-\epsilon n}) \). Lemma 4.1 shows that the probability that \( \mathcal{T} \) reaches a significant vertex and hence stops because of the first reason, is at most \( O(2^{-\epsilon n}) \). Assuming that \( \mathcal{T} \) doesn’t reach any significant vertex (in which case it would have stopped because of the first reason), Claim 4.2 shows that in each step, the probability that \( \mathcal{T} \) stops because of the second reason, is at most \( 2^{2-2\epsilon n} \). Taking a union bound over the \( m = 2^n \) steps, the total probability that \( \mathcal{T} \) stops because of the second reason, is at most \( 2^{-\epsilon n} \). In the same way, assuming that \( \mathcal{T} \) doesn’t reach any significant vertex (in which case it would have stopped because of the first reason), Claim 4.3 shows that in each step, the probability that \( \mathcal{T} \) stops because of the third reason, is at most \( 2^{2-2\epsilon n} \). Again, taking a union bound over the \( 2^n \) steps, the total probability that \( \mathcal{T} \) stops because of the third reason, is at most \( 2^{-\epsilon n} \). Thus, the total probability that \( \mathcal{T} \) stops (for any reason) before reaching a leaf is at most \( O(2^{-\epsilon n}) \).

Recall that if \( \mathcal{T} \) doesn’t stop before reaching a leaf, it just follows the computation-path of \( B \). Recall also that by Lemma 4.1, the probability that \( \mathcal{T} \) reaches a significant leaf is at most \( O(2^{-\epsilon n}) \). Thus, to bound (from above) the success probability of \( B \) by \( O(2^{-\epsilon n}) \), it remains to bound the probability that \( \mathcal{T} \) reaches a non-significant leaf \( v \) and \( \tilde{x}(v) = x \).

Claim 4.4 shows that for any non-significant leaf \( v \), conditioned on the event that \( \mathcal{T} \) reaches \( v \), the probability for \( \tilde{x}(v) = x \) is at most \( 2^{-\epsilon n} \), which completes the proof of Theorem 1.

Claim 4.4. If \( v \) is a non-significant leaf of \( B \) then

\[
\Pr[\tilde{x}(v) = x \mid E_v] \leq 2^{-\epsilon n}.
\]

Proof. Since \( v \) is not significant,

\[
\mathbb{E}_{x' \in R^X} \left[ \mathbb{P}_{x \mid v}(x')^2 \right] \leq 2^{2\delta n} \cdot 2^{-2n}.
\]

Hence, for every \( x' \in X \),

\[
\Pr[x = x' \mid E_v] = \mathbb{P}_{x \mid v}(x') \leq 2^{\delta n} \cdot 2^{-n/2} = 2^{-n} \cdot (\frac{1}{2} - \delta) < 2^{-\epsilon n}
\]

(since \( \epsilon < \frac{1}{2} - \delta \)). In particular,

\[
\Pr[\tilde{x}(v) = x \mid E_v] < 2^{-\epsilon n}.
\]

This completes the proof of Theorem 1.

\[\square\]

4.3 Proof of Lemma 4.1

Proof. We need to prove that the probability that \( \mathcal{T} \) reaches any significant vertex is at most \( O(2^{-\epsilon n}) \). Let \( s \) be a significant vertex of \( B \). We will bound from above the probability that \( \mathcal{T} \) reaches \( s \), and then use a union bound over all significant vertices of \( B \). Interestingly, the upper bound on the width of \( B \) is used only in the union bound.
The Distributions $\mathbb{P}_{x|v}$ and $\mathbb{P}_{x|e}$

Recall that for a vertex $v$ of $B$, we denote by $E_v$ the event that $\mathcal{T}$ reaches the vertex $v$. For simplicity, we denote by $\Pr(v) = \Pr(E_v)$ the probability for $E_v$ (where the probability is over $x, a_1, \ldots, a_m$), and we denote by $\mathbb{P}_{x|v} = \mathbb{P}_{x|E_v}$ the distribution of the random variable $x$ conditioned on the event $E_v$.

Similarly, for an edge $e$ of the branching program $B$, let $E_{e}$ be the event that $\mathcal{T}$ traverses the edge $e$. Denote, $\Pr(e) = \Pr(E_{e})$ (where the probability is over $x, a_1, \ldots, a_m$), and $\mathbb{P}_{x|e} = \mathbb{P}_{x|E_{e}}$.

Claim 4.5. For any edge $e = (v, u)$ of $B$, labeled by $(a, b)$, such that $\Pr(e) > 0$, for any $x' \in X$,

$$\mathbb{P}_{x|e}(x') = \begin{cases} 0 & \text{if } x' \in \text{Sig}(v) \text{ or } M(a, x') \neq b \\ \mathbb{P}_{x|v}(x') \cdot c_e^{-1} & \text{if } x' \not\in \text{Sig}(v) \text{ and } M(a, x') = b \end{cases}$$

where $c_e$ is a normalization factor that satisfies,

$$c_e > \frac{1}{2} - 2 \cdot 2^{-2\epsilon n}.$$  

Proof. Let $e = (v, u)$ be an edge of $B$, labeled by $(a, b)$, and such that $\Pr(e) > 0$. Since $\Pr(e) > 0$, the vertex $v$ is not significant (as otherwise $\mathcal{T}$ always stops on $v$ and hence $\Pr(e) = 0$). Also, since $\Pr(e) > 0$, we know that $a \not\in \text{Bad}(v)$ (as otherwise $\mathcal{T}$ never traverses $e$ and hence $\Pr(e) = 0$).

If $\mathcal{T}$ reaches $v$, it traverses the edge $e$ if and only if: $x \not\in \text{Sig}(v)$ (as otherwise $\mathcal{T}$ stops on $v$) and $M(a, x) = b$ and $a_{i+1} = a$. Therefore, for any $x' \in X$,

$$\mathbb{P}_{x|e}(x') = \begin{cases} 0 & \text{if } x' \in \text{Sig}(v) \text{ or } M(a, x') \neq b \\ \mathbb{P}_{x|v}(x') \cdot c_e^{-1} & \text{if } x' \not\in \text{Sig}(v) \text{ and } M(a, x') = b \end{cases}$$

where $c_e$ is a normalization factor, given by

$$c_e = \sum_{\{x' : x' \not\in \text{Sig}(v) \land M(a, x') = b\}} \mathbb{P}_{x|v}(x') = \Pr_x([x \not\in \text{Sig}(v)] \land [M(a, x) = b]) \mid E_v].$$

Since $v$ is not significant, by Claim 4.2,

$$\Pr_x[x \in \text{Sig}(v) \mid E_v] \leq 2^{-2\epsilon n}.$$  

Since $a \not\in \text{Bad}(v)$,

$$\left| \Pr_x[M(a, x) = 1 \mid E_v] - \Pr_x[M(a, x) = -1 \mid E_v] \right| = \left| (M \cdot \mathbb{P}_{x|v})(a) \right|$$

$$\leq 2^{(\delta + \gamma + \epsilon) n} \cdot 2^{-n}.$$  

and hence

$$\Pr_x[M(a, x) \neq b \mid E_v] \leq \frac{1}{2} + 2^{(\delta + \gamma + \epsilon) n} \cdot 2^{-n}.$$  

Hence, by the union bound,

$$c_e = \Pr_x([x \not\in \text{Sig}(v)] \land [M(a, x) = b]) \mid E_v] \geq \frac{1}{2} - 2^{(\delta + \gamma + \epsilon) n} \cdot 2^{-n} - 2^{-2\epsilon n} > \frac{1}{2} - 2 \cdot 2^{-2\epsilon n}$$

(where the last inequality follows since $3\epsilon < 1 - \delta - \gamma$).  

\qed
Bounding the Norm of $\|P_x|s\|_2$

We will show that $\|P_x|s\|_2$ cannot be too large. Towards this, we will first prove that for every edge $e$ of $B$ that is traversed by $T$ with probability larger than zero, $\|P_x|e\|_2$ cannot be too large.

**Claim 4.6.** For any edge $e$ of $B$, such that $\Pr(e) > 0$,

$$\|P_x|e\|_2 \leq 4 \cdot 2^{6n} \cdot 2^{-n}.$$  

**Proof.** Let $e = (v, u)$ be an edge of $B$, labeled by $(a, b)$, and such that $\Pr(e) > 0$. Since $\Pr(e) > 0$, the vertex $v$ is not significant (as otherwise $T$ always stops on $v$ and hence $\Pr(e) = 0$). Thus,

$$\|P_x|e\|_2 \leq 2^{6n} \cdot 2^{-n}.$$  

By Claim 4.5, for any $x' \in X$,

$$P_x|e(x') = \begin{cases} 0 & \text{if } x' \in \text{Sig}(v) \text{ or } M(a, x') \neq b \\ P_x|v(x') \cdot c_e^{-1} & \text{if } x' \notin \text{Sig}(v) \text{ and } M(a, x') = b \end{cases}$$

where $c_e$ satisfies,

$$c_e > \frac{1}{2} - 2 \cdot 2^{-2\epsilon n} > \frac{1}{4}$$

(where the last inequality holds because we assume that $n$ is sufficiently large).

Thus,

$$\|P_x|e\|_2 \leq c_e^{-1} \cdot \|P_x|v\|_2 \leq 4 \cdot 2^{6n} \cdot 2^{-n}.$$  

**Claim 4.7.**

$$\|P_x|s\|_2 \leq 4 \cdot 2^{6n} \cdot 2^{-n}.$$  

**Proof.** Let $\Gamma_{in}(s)$ be the set of all edges $e$ of $B$, that are going into $s$, such that $\Pr(e) > 0$. Note that

$$\sum_{e \in \Gamma_{in}(s)} \Pr(e) = \Pr(s).$$

By the law of total probability, for every $x' \in X$,

$$P_x|s(x') = \sum_{e \in \Gamma_{in}(s)} \Pr(e) \cdot P_x|e(x'),$$

and hence by Jensen’s inequality,

$$P_x|s(x')^2 \leq \sum_{e \in \Gamma_{in}(s)} \Pr(e) \cdot P_x|e(x')^2.$$  

Summing over $x' \in X$, we obtain,

$$\|P_x|s\|_2^2 \leq \sum_{e \in \Gamma_{in}(s)} \Pr(e) \cdot \|P_x|e\|_2^2.$$  

By Claim 4.6, for any $e \in \Gamma_{in}(s)$,

$$\|P_x|e\|_2^2 \leq (4 \cdot 2^{6n} \cdot 2^{-n})^2.$$  

Hence,

$$\|P_x|s\|_2^2 \leq (4 \cdot 2^{6n} \cdot 2^{-n})^2.$$  

$\square$
Similarity to a Target Distribution

For two functions $f, g : X \to \mathbb{R}^+$, define
\[ \langle f, g \rangle = \mathbb{E}_{z \in X} [f(z) \cdot g(z)]. \]

We think of $\langle f, g \rangle$ as a measure for the similarity between a function $f$ and a target function $g$. Typically $f, g$ will be distributions.

Claim 4.8.
\[ \langle \mathbb{P}_{x|s}, \mathbb{P}_{x|s} \rangle > 2^{26n} \cdot 2^{-2n}. \]

Proof. Since $s$ is significant,
\[ \langle \mathbb{P}_{x|s}, \mathbb{P}_{x|s} \rangle = \|\mathbb{P}_{x|s}\|_2^2 > 2^{26n} \cdot 2^{-2n}. \]

Claim 4.9.
\[ \langle U_X, \mathbb{P}_{x|s} \rangle = 2^{-2n}, \]
where $U_X$ is the uniform distribution over $X$.

Proof. Since $\mathbb{P}_{x|s}$ is a distribution,
\[ \langle U_X, \mathbb{P}_{x|s} \rangle = 2^{-2n} \cdot \sum_{z \in X} \mathbb{P}_{x|s}(z) = 2^{-2n}. \]

Measuring the Progress

For $i \in \{0, \ldots, m\}$, let $L_i$ be the set of vertices $v$ in layer-$i$ of $B$, such that $\Pr(v) > 0$. For $i \in \{1, \ldots, m\}$, let $\Gamma_i$ be the set of edges $e$ from layer-$(i - 1)$ of $B$ to layer-$i$ of $B$, such that $\Pr(e) > 0$. Recall that $\beta$ was fixed at the beginning of the proof of Theorem 1. For $i \in \{0, \ldots, m\}$, let
\[ Z_i = \sum_{v \in L_i} \Pr(v) \cdot \langle \mathbb{P}_{x|v}, \mathbb{P}_{x|s} \rangle^{\beta n}. \]

For $i \in \{1, \ldots, m\}$, let
\[ Z'_i = \sum_{e \in \Gamma_i} \Pr(e) \cdot \langle \mathbb{P}_{x|e}, \mathbb{P}_{x|s} \rangle^{\beta n}. \]

We think of $Z_i, Z'_i$ as measuring the progress made by the branching program, towards reaching a state with distribution similar to $\mathbb{P}_{x|s}$.

For a vertex $v$ of $B$, let $\Gamma_{\text{out}}(v)$ be the set of all edges $e$ of $B$, that are going out of $v$, such that $\Pr(e) > 0$. Note that
\[ \sum_{e \in \Gamma_{\text{out}}(v)} \Pr(e) \leq \Pr(v). \]

(We don’t always have an equality here, since sometimes $T$ stops on $v$).

The next four claims show that the progress made by the branching program is slow.
Claim 4.10. For every vertex \(v\) of \(B\), such that \(\text{Pr}(v) > 0\),
\[
\sum_{e \in \Gamma_{out}(v)} \Pr(e) \cdot \langle \mathbb{P}_{x|e}, \mathbb{P}_{x|s} \rangle^{\beta n} \leq \langle \mathbb{P}_{x|v}, \mathbb{P}_{x|s} \rangle^{\beta n} \cdot (1 + 2^{-1.9n}) + (2^{-2n+2})^{\beta n}.
\]

Proof. If \(v\) is significant or \(v\) is a leaf, then \(T\) always stops on \(v\) and hence \(\Gamma_{out}(v)\) is empty and thus the left hand side is equal to zero and the right hand side is positive, so the claim follows trivially. Thus, we can assume that \(v\) is not significant and is not a leaf.

Define \(P : X \to \mathbb{R}^+\) as follows. For any \(x' \in X\),
\[
P(x') = \begin{cases} 
0 & \text{if } x' \in \text{Sig}(v) \\
\mathbb{P}_{x|v}(x') & \text{if } x' \notin \text{Sig}(v)
\end{cases}
\]
Note that by the definition of \(\text{Sig}(v)\), for any \(x' \in X\),
\[
P(x') \leq 2^{2(\delta+\epsilon)n} \cdot 2^{-n}. \tag{1}
\]

Define \(f : X \to \mathbb{R}^+\) as follows. For any \(x' \in X\),
\[
f(x') = P(x') \cdot \mathbb{P}_{x|s}(x').
\]

By Claim 4.7 and Equation (1),
\[
\|f\|_2 \leq 2^{2(\delta+\epsilon)n} \cdot 2^{-n} \cdot \|\mathbb{P}_{x|s}\|_2 \leq 2^{(\delta+\epsilon)n} \cdot 2^{-n} \cdot 4 \cdot 2^{\beta n} \cdot 2^{-n} = 2^{(3\delta+2\epsilon)n+2} \cdot 2^{-2n}. \tag{2}
\]

By Claim 4.5, for any edge \(e \in \Gamma_{out}(v)\), labeled by \((a, b)\), for any \(x' \in X\),
\[
\mathbb{P}_{x|e}(x') = \begin{cases} 
0 & \text{if } M(a, x') \neq b \\
\mathbb{P}(x') \cdot c_e^{-1} & \text{if } M(a, x') = b
\end{cases}
\]

where \(c_e\) satisfies,
\[
c_e > \frac{1}{2} - 2 \cdot 2^{-2\epsilon n}.
\]
Therefore, for any edge \(e \in \Gamma_{out}(v)\), labeled by \((a, b)\), for any \(x' \in X\),
\[
\mathbb{P}_{x|e}(x') \cdot \mathbb{P}_{x|s}(x') = \begin{cases} 
0 & \text{if } M(a, x') \neq b \\
f(x') \cdot c_e^{-1} & \text{if } M(a, x') = b
\end{cases}
\]

and hence, denoting
\[
F = \sum_{x' \in X} f(x'),
\]
we have
\[
\mathbb{E}_{x' \in \mathbb{R}^X} [\mathbb{P}_{x|e}(x') \cdot \mathbb{P}_{x|s}(x')] = c_e^{-1} \cdot 2^{-n} \cdot \sum_{\{x' : M(a, x') = b\}} f(x') = c_e^{-1} \cdot 2^{-n} \cdot \frac{\mathbb{E}(F + \mathbb{E}(M \cdot f)(a))}{2}
\]
\[
\leq (2 \cdot c_e)^{-1} \cdot 2^{-n} \cdot (F + \mathbb{E}(M \cdot f)(a)) < 2^{-n} \cdot (F + \mathbb{E}(M \cdot f)(a)) \cdot (1 + 2^{-2\epsilon n+3}) \tag{3}
\]
(where the last inequality holds by the bound that we have on \(c_e\), because we assume that \(n\) is sufficiently large).

We will now consider two cases:
Case I: $F \leq 2^{-n}$

In this case, we bound $|(M \cdot f)(a)| \leq F$ (since $f$ is non-negative and the entries of $M$ are in $\{-1, 1\}$) and $(1 + 2^{-2n+3}) < 2$ (since we assume that $n$ is sufficiently large) and obtain for any edge $e \in \Gamma_{out}(v)$,

$$\langle \mathbb{P}_{x|e}, \mathbb{P}_{x|s} \rangle < 4 \cdot 2^{-2n}.$$  

Since $\sum_{e \in \Gamma_{out}(v)} \frac{Pr(e)}{Pr(v)} \leq 1$, Claim 4.10 follows, as the left hand side of the claim is smaller than the second term on the right hand side.

Case II: $F \geq 2^{-n}$

For every $a \in A$, define

$$t(a) = \left( \frac{(M \cdot f)(a)}{F} \right)^2.$$  

By Equation (3),

$$\langle \mathbb{P}_{x|e}, \mathbb{P}_{x|s} \rangle^{\beta_n} < (2^{-n} \cdot F)^{\beta_n} \cdot \left(1 + \sqrt{t(a)}\right)^{\beta_n} \cdot (1 + 2^{-2n+3})^{\beta_n}. \quad (4)$$

Note that by the definitions of $P$ and $f$,

$$2^{-n} \cdot F = \mathbb{E}_{x' \in \mathcal{R}^X}[f(x')] = \langle P, \mathbb{P}_{x|s} \rangle \leq \langle \mathbb{P}_{x|v}, \mathbb{P}_{x|s} \rangle.$$  

Note also that for every $a \in A$, there is at most one edge $e_{(a,1)} \in \Gamma_{out}(v)$, labeled by $(a, 1)$, and at most one edge $e_{(a,-1)} \in \Gamma_{out}(v)$, labeled by $(a, -1)$, and we have

$$\frac{Pr(e_{(a,1)})}{Pr(v)} + \frac{Pr(e_{(a,-1)})}{Pr(v)} \leq \frac{1}{|A|},$$  

since $\frac{1}{|A|}$ is the probability that the next sample read by the program is $a$. Thus, summing over all $e \in \Gamma_{out}(v)$, by Equation (4),

$$\sum_{e \in \Gamma_{out}(v)} \frac{Pr(e)}{Pr(v)} \langle \mathbb{P}_{x|e}, \mathbb{P}_{x|s} \rangle^{\beta_n} \leq \langle \mathbb{P}_{x|v}, \mathbb{P}_{x|s} \rangle^{\beta_n} \cdot \mathbb{E}_{a \in \mathcal{R}^A} \left[ 1 + \sqrt{t(a)} \right]^{\beta_n} \cdot (1 + 2^{-2n+3})^{\beta_n}. \quad (5)$$

It remains to bound

$$\mathbb{E}_{a \in \mathcal{R}^A} \left[ 1 + \sqrt{t(a)} \right]^{\beta_n}, \quad (6)$$

where for every $a \in A$, $0 \leq t(a) \leq 1$, under the constraint

$$\mathbb{E}_{a \in \mathcal{R}^A}[t(a)] \leq 2^{-(2-2\gamma-6\delta-4\epsilon)n+4}, \quad (7)$$

which follows since, by Equation (2) and the assumption $F \geq 2^{-n}$, we have

$$\mathbb{E}_{a \in \mathcal{R}^A}[t(a)] = \mathbb{E}_{a \in \mathcal{R}^A} \left[ \left( \frac{(M \cdot f)(a)}{F} \right)^2 \right] = \frac{\|M \cdot f\|_2^2}{F^2} \leq \frac{\|M\|_2^2 \cdot \|f\|_2^2}{F^2} \leq \left( \frac{2^{\gamma n} \cdot 2^{(3\delta+2\epsilon)n+2} \cdot 2^{-2n}}{2^{-n}} \right)^2 = 2^{-(2-2\gamma-6\delta-4\epsilon)n+4}.$$
We will bound the expectation in Equation (6), by splitting the expectation into two sums
\[
\mathbb{E}_{a \in R^d} \left[ \left( 1 + \sqrt{t(a)} \right)^{\beta n} \right] =
\]
\[
\frac{1}{|A|} \cdot \sum_{a : t(a) \leq \frac{1}{(\beta n - 2)^2}} \left( 1 + \sqrt{t(a)} \right)^{\beta n} + \frac{1}{|A|} \cdot \sum_{a : t(a) > \frac{1}{(\beta n - 2)^2}} \left( 1 + \sqrt{t(a)} \right)^{\beta n}.
\] (8)

To bound the first sum in Equation (8), we note that in the range \( 0 \leq t \leq \frac{1}{(\beta n - 2)^2} \), the function \( g(t) = (1 + \sqrt{t})^{\beta n} \) is concave (since its second derivative is negative). Hence, by Equation (7) and by the monotonicity of \( g \),
\[
\frac{1}{|A|} \cdot \sum_{a : t(a) \leq \frac{1}{(\beta n - 2)^2}} \left( 1 + \sqrt{t(a)} \right)^{\beta n} \leq \left( 1 + \sqrt{2^{-(2-2\gamma - 6\delta - 4\epsilon)n + 4}} \right)^{\beta n}
\]
\[
= (1 + 2^{-((1-\gamma - 3\delta - 2\epsilon)n + 2)})^{\beta n} < 1 + 2^{-(1-\gamma - 3\delta - 2\epsilon)n} < 1 + 2^{\epsilon n}
\] (9)
(where the last two inequalities hold because we assume that \( n \) is sufficiently large and \( 5\epsilon < 1 - \gamma - 3\delta \)).

To bound the second sum in Equation (8), we note that by Equation (7) and Markov’s inequality,
\[
\mathbb{P}_{a \in R^d} \left[ t(a) > \frac{1}{(\beta n - 2)^2} \right] \leq 2^{-(2-2\gamma - 6\delta - 4\epsilon)n + 4} \cdot (\beta n - 2)^2 < 2^{-(2-2\gamma - 6\delta - 5\epsilon)n}
\]
(where the last inequality holds because we assume that \( n \) is sufficiently large), and since for every \( a \in A \), we have \( t(a) \leq 1 \),
\[
\frac{1}{|A|} \cdot \sum_{a : t(a) > \frac{1}{(\beta n - 2)^2}} \left( 1 + \sqrt{t(a)} \right)^{\beta n} < 2^{-(2-2\gamma - 6\delta - 5\epsilon)n} \cdot 2^{\beta n} = 2^{-(2-2\gamma - 6\delta - 5\epsilon)n} < 2^{-5\epsilon n}
\] (10)
(where the last inequality holds because \( 10\epsilon < 2 - 2\gamma - 6\delta \)).

Substituting Equation (9) and Equation (10) into Equation (8) and substituting this into Equation (5), we obtain
\[
\sum_{e \in \Gamma_{out}(v)} \mathbb{P}(e) \cdot \mathbb{E}_{x|v}^e \cdot \mathbb{E}_{x|s}^e \leq \mathbb{E}_{x|v} \cdot \mathbb{E}_{x|s} \cdot \left( 1 + 2^{\epsilon n + 3} \right)^{\beta n + 1}
\]
\[
< \mathbb{E}_{x|v} \cdot \mathbb{E}_{x|s} \cdot \left( 1 + 2^{-1.9\epsilon n} \right)
\]
(where the last inequality holds because we assume that \( n \) is sufficiently large).

This completes the proof of Claim 4.10. \( \square \)

Claim 4.11. For every \( i \in \{1, \ldots, m\} \),
\[
Z_i' \leq Z_{i-1} \cdot \left( 1 + 2^{-1.9\epsilon n} \right) + (2^{-2\epsilon n + 2})^{\beta n}.
\]
Proof. By Claim 4.10,
\[ Z_i' = \sum_{e \in \Gamma_i} \Pr(e) \cdot \langle P_{x|e}, P_{x|s} \rangle^{\beta n} = \sum_{v \in L_{i-1}} \Pr(v) \cdot \sum_{e \in \Gamma_{\text{out}}(v)} \frac{\Pr(e)}{\Pr(v)} \cdot \langle P_{x|e}, P_{x|s} \rangle^{\beta n} \]
\[ \leq \sum_{v \in L_{i-1}} \Pr(v) \cdot \left( \langle P_{x|e}, P_{x|s} \rangle^{\beta n} \cdot (1 + 2^{-1.9 \cdot n}) + (2^{-2n+2})^{\beta n} \right) \]
\[ = Z_{i-1} \cdot (1 + 2^{-1.9 \cdot n}) + \sum_{v \in L_{i-1}} \Pr(v) \cdot (2^{-2n+2})^{\beta n} \]
\[ \leq Z_{i-1} \cdot (1 + 2^{-1.9 \cdot n}) + (2^{-2n+2})^{\beta n} \]
\[ \square \]

Claim 4.12. For every \( i \in \{1, \ldots, m\} \),
\[ Z_i \leq Z_i'. \]

Proof. For any \( v \in L_i \), let \( \Gamma_{\text{in}}(v) \) be the set of all edges \( e \in \Gamma_i \), that are going into \( v \). Note that
\[ \sum_{e \in \Gamma_{\text{in}}(v)} \Pr(e) = \Pr(v). \]

By the law of total probability, for every \( v \in L_i \) and every \( x' \in X \),
\[ P_{x|v}(x') = \sum_{e \in \Gamma_{\text{in}}(v)} \frac{\Pr(e)}{\Pr(v)} \cdot P_{x|e}(x'), \]
and hence
\[ \langle P_{x|v}, P_{x|s} \rangle = \sum_{e \in \Gamma_{\text{in}}(v)} \frac{\Pr(e)}{\Pr(v)} \cdot \langle P_{x|e}, P_{x|s} \rangle. \]

Thus, by Jensen’s inequality,
\[ \langle P_{x|v}, P_{x|s} \rangle^{\beta n} \leq \sum_{e \in \Gamma_{\text{in}}(v)} \frac{\Pr(e)}{\Pr(v)} \cdot \langle P_{x|e}, P_{x|s} \rangle^{\beta n}. \]

Summing over all \( v \in L_i \), we get
\[ Z_i = \sum_{v \in L_i} \Pr(v) \cdot \langle P_{x|v}, P_{x|s} \rangle^{\beta n} \leq \sum_{v \in L_i} \Pr(v) \cdot \sum_{e \in \Gamma_{\text{in}}(v)} \frac{\Pr(e)}{\Pr(v)} \cdot \langle P_{x|e}, P_{x|s} \rangle^{\beta n} \]
\[ = \sum_{e \in \Gamma_i} \Pr(e) \cdot \langle P_{x|e}, P_{x|s} \rangle^{\beta n} = Z_i'. \]
\[ \square \]

Claim 4.13. For every \( i \in \{1, \ldots, m\} \),
\[ Z_i \leq 2^{2(\beta+\epsilon)n} \cdot 2^{-2\beta n^2}. \]

Proof. By Claim 4.9, \( Z_0 = (2^{-2n})^{\beta n} \). By Claim 4.11 and Claim 4.12, for every \( i \in \{1, \ldots, m\} \),
\[ Z_i \leq Z_{i-1} \cdot (1 + 2^{-1.9 \cdot n}) + (2^{-2n+2})^{\beta n}. \]

Hence, for every \( i \in \{1, \ldots, m\} \),
\[ Z_i \leq (2^{-2n+2})^{\beta n} \cdot m \cdot (1 + 2^{-1.9 \cdot n})^{m}. \]

Since \( m = 2^{en} \),
\[ Z_i \leq 2^{-2\beta n^2} \cdot 2^{2\beta n} \cdot 2^{en} \cdot 2 \leq 2^{-2\beta n^2} \cdot 2^{2(\beta+\epsilon)n}. \]
\[ \square \]
Proof of Lemma 4.1

We can now complete the proof of Lemma 4.1. Assume that \( s \) is in layer-\( i \) of \( B \). By Claim 4.8,
\[
Z_i \geq \Pr(s) \cdot \langle P_{x|s}, P_{x|s} \rangle^{\beta n} > \Pr(s) \cdot (2^{2\delta n} \cdot 2^{-2n})^{\beta n} = \Pr(s) \cdot 2^{2\delta \beta n^2} \cdot 2^{-2\beta n^2}.
\]

On the other hand, by Claim 4.13,
\[
Z_i \leq 2^{2(\beta + \epsilon)n} \cdot 2^{-2\beta n^2}.
\]

Thus,
\[
\Pr(s) \leq 2^{2(\beta + \epsilon)n} \cdot 2^{-2\beta n^2}.
\]

We will fix \( \beta' \) to be any constant smaller than 1 and \( \delta' \) to be any constant smaller than \( \frac{1}{6} \) (note that the requirement \( \beta' + 6\delta' < 2 \) is satisfied and recall that \( \delta = \delta' \cdot (1 - \gamma) \) and \( \beta = \beta' \cdot (1 - \gamma) \)), to obtain
\[
\Pr(s) \leq 2^{-\tilde{c}(1-\gamma)^2 n^2},
\]
for any constant \( \tilde{c} < \frac{1}{3} \) (where we assumed that \( n \) is sufficiently large).

Taking a union bound over at most \( 2^{\epsilon n} \cdot 2^{cn^2} \) significant vertices of \( B \), we conclude that the probability that \( T \) reaches any significant vertex is at most \( 2^{-\Omega(n^2)} \) (as \( c < c' \cdot (1 - \gamma)^2 \), where \( c' \) is a constant smaller than \( \frac{1}{3} \)). Since we assume that \( n \) is sufficiently large, \( 2^{-\Omega(n^2)} \) is certainly at most \( 2^{-\epsilon n} \).
