Finding forbidden minors in sublinear time: a $n^{1/2+o(1)}$-query one-sided tester for minor closed properties on bounded degree graphs

Akash Kumar∗ C. Seshadhri† Andrew Stolman‡

Abstract

Let $G$ be an undirected, bounded degree graph with $n$ vertices. Fix a finite graph $H$, and suppose one must remove $\varepsilon n$ edges from $G$ to make it $H$-minor free (for some small constant $\varepsilon > 0$). We give an $n^{1/2+o(1)}$-time randomized procedure that, with high probability, finds an $H$-minor in such a graph. As an application, suppose one must remove $\varepsilon n$ edges from a bounded degree graph $G$ to make it planar. This result implies an algorithm, with the same running time, that produces a $K_{3,3}$ or $K_5$ minor in $G$. No prior sublinear time bound was known for this problem.

By the graph minor theorem, we get an analogous result for any minor-closed property. Up to $n^{o(1)}$ factors, this resolves a conjecture of Benjamini-Schramm-Shapira (STOC 2008) on the existence of one-sided property testers for minor-closed properties. Furthermore, our algorithm is nearly optimal, by an $\Omega(\sqrt{n})$ lower bound of Czumaj et al (RSA 2014).

Prior to this work, the only graphs $H$ for which non-trivial one-sided property testers were known for $H$-minor freeness are the following: $H$ being a forest or a cycle (Czumaj et al, RSA 2014), $K_{2,k}$, $(k \times 2)$-grid, and the $k$-circus (Fichtenberger et al, Arxiv 2017).

1 Introduction

Deciding if an $n$-vertex graph $G$ is planar is a classic algorithmic problem solvable in linear time [HT74]. The Kuratowski-Wagner theorem asserts that any non-planar graph must contain a $K_5$ or $K_{3,3}$-minor [Kur30, Wag37]. Thus, certifying non-planarity is equivalent to producing such a minor, which can be done in linear time. Can we beat the linear time bound if we knew that $G$ was “sufficiently” non-planar?

Assume random access to an adjacency list representation of a bounded degree graph, $G$. Suppose, for some constant $\varepsilon > 0$, one had to remove $\varepsilon n$ edges from $G$ to make it planar. Can one find a forbidden ($K_5$ or $K_{3,3}$) minor in $o(n)$ time? It is natural to ask this question for any property expressible through forbidden minors. By the famous Robertson-Seymour graph minor theorem [RS04], any graph property $P$ that is closed under taking minors can be expressed by a finite list of forbidden minors. We desire sublinear time algorithms to find a forbidden minor in any $G$ that requires $\varepsilon n$ edge deletions to make it have $P$.

This problem was first posed by Benjamini-Schramm-Shapira [BSS08] in the context of property testing on bounded degree graphs. We follow the model of property testing on bounded-degree graphs as defined by Goldreich-Ron [GR02]. Fix a degree bound $d$. Consider $G = (V,E)$, where $V = [n]$, and $G$ is represented by an adjacency list. We have random access to the list through neighbor queries. There is an oracle that, given $v \in V$ and $i \in [d]$, returns the $i$th neighbor of $v$ (if no neighbor exists, it returns $\perp$).

Given any property $P$ of graphs with degree bound $d$, the distance of $G$ to $P$ is defined to be the minimum number of edge additions/removals required to make $G$ have $P$, divided by $dn$. This ensures that the distance is in $[0,1]$. We say that $G$ is $\varepsilon$-far from $P$ if the distance to $P$ is more than $\varepsilon$.

A property tester for $P$ is a randomized procedure takes as input (query access to) $G$ and a proximity parameter $\varepsilon > 0$. If $G \in P$, the tester must accept with probability at least $2/3$. If $G$ is $\varepsilon$-far from $P$, the tester must reject with probability at least $2/3$. A one-sided tester must accept $G \in P$ with probability 1, and thus provide a certificate of rejection.

We are interested in property $P$ expressible through forbidden minors. Fix a finite graph $H$. The property $P_H$ of $H$-minor freeness is the set of graphs that do not contain $H$ as a minor. Observe that one-sided testers for $P_H$ have a special significance since they must produce an $H$-minor whenever they reject. One can cast one-sided property testers as sublinear time procedures that find forbidden minors. Our main theorem follows.

**Theorem 1.1.** Fix a finite graph $H$ with $|V(H)| = r$ and arbitrarily small $\delta > 0$. Let $P_H$ be the property of $H$-minor freeness. There is a randomized algorithm that takes as input (oracle access to) a graph $G$ with maximum degree $d$, and a parameter $\varepsilon > 0$. Its running time is $dn^{1/2+O(\delta r^4)} + d\varepsilon^{-2\exp(2/\delta)/\delta}$. If $G$ is $\varepsilon$-far from $P_H$, then, with probability $> 2/3$, the algorithm outputs an $H$-minor in $G$.

Equivalently, there exists a one-sided property tester for $P_H$ with the above running time.

The graph-minor theorem of Robertson and Seymour [RS04] asserts the following. Consider any property $Q$ that is closed under taking minors. There is a finite list $H$ of graphs such that $G \in Q$ iff $G$ is $H$-minor free for all $H \in H$. If $G$ is $\varepsilon$-far from $Q$, then $G$ is $\Omega(\varepsilon)$-far from $P_H$ for some $H \in H$. Thus, a direct corollary of Theorem 1.1 is the following.

**Corollary 1.2.** Let $Q$ be any minor-closed property of graphs with degree bound $d$. For any $\delta > 0$, there is a one-sided property tester for $Q$ with running time $O(dn^{1/2+\delta} + d\varepsilon^{-2\exp(2/\delta)/\delta})$. 

1
In the following discussion, we suppress dependences on $\varepsilon$ and $n^\delta$ by $O^*(\cdot)$ (where $\delta > 0$ is arbitrarily small). Previously, the only graphs $H$ for which an analogue of Theorem 1.1 was known are the following: $O^*(1)$ time for $H$ being a forest, $O^*(\sqrt{n})$ for $H$ being a cycle [CGR$^+$14], and $O^*(n^{2/3})$ for $H$ being $K_{2,k}$, the $(k \times 2)$-grid, and the $k$-circus [FLVW17]. No sublinear time bound was known for planarity.

Corollary 1.2 implies that properties such as planarity, series-parallel graphs, embeddability in bounded genus surfaces, and bounded treewidth are all one-sided testable in $O^*(\sqrt{n})$ time.

We note a particularly pleasing application of Theorem 1.1. Suppose bounded degree $G$ has more than $(3 + \varepsilon)n$ edges. Then it is guaranteed to be $\varepsilon$-far from being planar, and thus, there is an algorithm to find a forbidden minor in $G$ in $O^*(\sqrt{n})$ time. Since all minor-closed properties have constant average degree bounds, analogous statements can be made for all such properties.

1.1 Related work

Graph minor theory is a deep topic, and we refer the reader to Chapter 12 of Diestel’s book [Die10] and Lovász’ survey [Lov06]. For our purposes, we use as a black-box polynomial time algorithms that find fixed minors in a graph. A result of Kawarabayashi-Kobayashi-Reed provides an $O(n^2)$ time algorithm [KKR12].

Property testing on graphs is an immensely rich area of study, and we refer the reader to Goldreich’s recent textbook for more details [Gol17]. There is a significant difference between the theory of property testing for dense graphs and that of bounded-degree graphs. For the former, there is a complete characterization of properties (one-sided, non-adaptive) testable in query complexity independent of graph size. There is a deep connection between property testing and the Szemerédi regularity lemma [AFNS06]. Property testing for bounded degree graphs is much less understood. This study was initiated by Goldreich-Ron, and the first results focused on connectivity properties [GR02]. Czumaj-Sohler-Shapira proved that hereditary properties of non-expanding graphs are testable [CSS09]. A breakthrough result of Benjamini-Schramm-Shapira (henceforth BSS) proved that all minor-closed (more generally, hyperfinite) properties are two-sided testable in constant time. The dependence on $\varepsilon$ was subsequently improved by Hassidim et al, using the concept of local partitioning oracles [HKNO09]. A result of Levi-Ron [LR15] significantly simplified and improved this analysis, to get a final query complexity quasi-polynomial in $1/\varepsilon$. Indeed, it is a major open question to get polynomial dependence on $1/\varepsilon$ for two-sided planarity testers. Towards this goal, Ito and Yoshida give such a bound for testing outerplanarity [YI15], or Edelman et al generalize for bounded treewidth graphs [EHN011].

In contrast to dense graph testing, there is a significant jump in complexity for one-sided testers. BSS first raised the question of one-sided testers for minor-closed properties (especially planarity) and conjectured that the bound is $O(\sqrt{n})$. Czumaj et al [CGR$^+$14] made the first step by giving an $\tilde{O}(\sqrt{n})$ one-sided tester for the property of being $C_k$-minor free [CGR$^+$14]. For $k = 3$, this is precisely the class of forests. This tester is obtained by a reduction to a much older result of Goldreich-Ron for one-sided bipartiteness testing for bounded degree graphs [GR99]. (The results in Czumaj et al are obtained by black-box applications of this result.) Czumaj et al adapt the one-sided $\Omega(\sqrt{n})$ lower bound for bipartiteness and show an $\Omega(\sqrt{n})$ lower bound for one-sided testers for $H$-minor freeness when $H$ has a cycle [CGR$^+$14]. This is complemented with a constant time tester for $H$-minor freeness when $H$ is a forest.

Recently, Fichtenberger-Levi-Vasudev-Wötzl give an $\tilde{O}(n^{2/3})$ tester for $H$-minor freeness when $H$ is one of the following graphs: $K_{2,k}$, the $(k \times 2)$-grid or the $k$-circus graph (a wheel where spokes
have two edges) [FLVW17]. This subsumes the properties of outerplanarity and cactus graphs. This result uses a different, more combinatorial (as opposed to random walk based) approach than Czumaj et al.

The use of random walks in property testing was pioneered by Goldreich-Ron [GR99] and was then (naturally) used in testing expansion properties and clustering structure [GR00, CS10, KS08, NS07, KPS13, CPS15]. Our approach is inspired by the Goldreich-Ron analysis, and we discuss more in the next section. A number of previous results have used random walks for routing in expanders [BFU99, KR96]. We use techniques from Kale-Seshadhri-Peres to analyze random walks on projected Markov Chains [KPS13]. We also employ the local partitioning methods of Spielman-Teng [ST12], which is in turn derived from the Lovász-Simonovits analysis technique [LS90].

2 Main Ideas

We give an overview of the proof strategy and discuss the various moving parts of the proof. For convenience, assume that $G$ is a $d$-regular graph. It is instructive to understand the method of Goldreich-Ron (henceforth GR) for one-side bipartiteness testing [GR99]. The basic idea to perform $O(\sqrt{n})$ random walks of poly($\log n$) length from a war vertex $s$. An odd cycle is discovered when two walks end at the same vertex $v$, through path of differing parity (of length).

The GR analysis first considers the case when $G$ is an expander (and $\varepsilon$-far from bipartite). In this case, the walks from $s$ reach the stationary distribution. One can use a standard collision argument to show that $O(\sqrt{n})$ suffice to hit the same vertex $v$ twice, with different parity paths. The deep insight is that any graph $G$ can be decomposed into pieces where the algorithm works, and each piece $P$ has a small cut to $P$. This has connections with decomposing a graph into expander-like pieces [Tre05, GT12]. Famously, the Arora-Barak-Steurer algorithm [ABS15] for unique games basically proves such a statement. We note that GR does not decompose into expanders, but rather into pieces where the expander analysis goes through. So, one might hope to analyze the algorithm by its behavior on each component. Unfortunately, the algorithm cannot produce the decomposition; it can only walk in $G$ and hope that performing random walks in $G$ suffice to simulate the procedure within $P$. This is extremely challenging, and is precisely what GR achieve (this is the bulk of the analysis). The main lemma produces a decomposition into such pieces, such that for each piece $P$, there exists $s \in P$ wherein short random walks (in $G$) from $s$ reach all vertices in $P$ with sufficient probability. One can think of this as a simulation argument: we would like to simulate the random walk algorithm running only on $P$, through random walks in $G$.

The challenge of general minors: With planarity in mind, let us focus on finding $K_5$ minors. It is highly unlikely that random walks from a single vertex will find a such a minor. Intuitively, we would need to find 5 different vertices, launch random walks from all of them and hope these walks will produce a minor. Thus, we would need to simulate a much more complex procedure than the (odd) cycle finder of GR. Most significantly, we need to understand the random walks behavior from multiple sources within $P$ simultaneously. The GR analysis actually constructs the pieces $P$ by a local partitioning looking at the random walk distribution from a single vertex. There is no guarantee on random walk behavior from other vertices in $P$.

There is a more significant challenge from arbitrary minors. The simulation does not say anything about the specific structure of the paths generated. It only deals with the probability of reaching $v$ from $s$ by a random walk in $G$ when $v$ and $s$ are in the same piece. For bipartiteness, as long as we find two paths of differing parity, we are done. They may intersect each other arbitrarily.
For finding a $K_5$ minor, the actual intersection behavior. We would need paths between all pairs of 5 seed vertices to be “disjoint enough” to give a $K_5$ minor. This appears extremely difficult using the GR analysis. Even if we did understand the random walk behavior (in $G$) from all vertices in $P$, we have little control over their behavior when they leave $P$. (Based on the parameters, the walks leave $P$ with high probability.) They may intersect arbitrarily, and thus destroy any minor structure.

### 2.1 When do random walks find minors?

Inspired by GR, let us start with an algorithm to find a $K_5$ minor in an expander $G$. (Variants of these ideas were present in a result of Kleinberg-Rubinfeld that expanders contain an $H$-minor for any $H$ with $n/poly\log n$ edges [KR96].) Let $\ell$ denote the mixing time. Pick u.a.r. a vertex $s$, and launch 5 random walks each of length $\ell$ to reach $v_1, v_2, \ldots, v_5$. From each $v_i$, launch $\sqrt{n}$ random walks each of length $\ell$. With high probability, a walk from $v_i$ and a walk from $v_j$ will “collide” (end at the same vertex). We can collect these collisions to get paths between all $v_i, v_j$, and one can, with some effort, show that these form a $K_5$-minor.

Our main insight is to show that this algorithm, with minor modifications, works even when random walks have extremely slow mixing properties. When the random walks mix even more slowly than the requisite bound, we can essentially perform local partitioning to pull out very small random walks have extremely slow mixing properties. When the random walks mix even more than (roughly speaking) spreads to a set of size $n^{1/2}$, we might hope that $\sum_{v \sim \mathcal{P}} \|p_s,\ell v\|^2 = \mathbb{E}_{v \sim \mathcal{P}} \|p_{v,\ell} v\|^2$. Thus, we would like these dot products to be large. By the slow case, random walks are hardly mixing by any standard of convergence. We are merely requiring that a random walk of length $n^{1/2}$ (roughly speaking) spreads to a set of size $n^{1/2}$.

We prove that, in the leaky case, the procedure described in the first paragraph succeeds in finding a $K_5$ with high probability. We give an outline of this proof strategy.

Let us assume that $p_{s,\ell/2} = p_{v,\ell}$ (so $\ell$-length walks have “stabilized”). Let us make a slight modification to the algorithm. We pick $v_1, \ldots, v_5$ as before, with $\ell$-length random walks from $s$. We will perform $O(\sqrt{n}) \ell/2$ length random walks from each $v_i$ to produce the $K_5$ minor. By symmetry of the random walks, the probability that a single walk from $v_i$ and one from $v_j$ collide (to produce a path) is exactly $p_{v_i,\ell/2} \cdot p_{v_j,\ell/2}$. Thus, we would like these dot products to be large. By the symmetry of the random walk, the probability of an $\ell$-length random walk starting from $s$ and ending at $v$ is $p_{s,\ell/2} \cdot p_{v,\ell/2}$.

Think of the dot products as correlations between distributions. We are saying that the average correlation (over some distribution on vertices) of $p_{v,\ell/2}$ with $p_{s,\ell/2}$ is exactly the self-correlation of $p_{s,\ell/2}$. If the distributions by and large had low $\ell_2$-norm (as in the leaky case), we might hope that these distributions are reasonably correlated with each other. Indeed, this is what we prove. Under some conditions, we show that $\mathbb{E}_{v_1 \sim \mathcal{P}} p_{s,\ell/2} \cdot p_{v_j,\ell/2}$ can be lower bounded, and $p_{v_i,\ell/2}$ is exactly the distribution the algorithm picks the $v_i$’s from. This is evidence that $\ell/2$-length random
walks will connect the \( v_i \)'s through collisions.

There are four difficulties in increasing order of worry.

1. We only have a lower bound of the average \( p_{v_i,\ell/2} \cdot p_{v_j,\ell/2} \). We would need bounds for all (or most) pairs to produce a minor.

2. \( p_{v,\ell} \) might be very different from \( p_{v,\ell/2} \).

3. The expected number of collisions between walks from \( v_i \) and \( v_j \) is controlled by the dot product above, but the variance (which really controls the probability of getting a collision) can be large. There are instances where the dot product is high, but the collision probability is extremely low.

4. There is no guarantee that these paths will produce a minor since we do not have any obvious constraints on the intermediate vertices in the path.

The first problem is surmounted by a technical trick. It turns out to be cleaner to analyze the probability of getting a biclique minor. So, we perform 50 random walks from \( s \) to get sets \( A = \{a_1, a_2, \ldots, a_{25}\} \) and an analogous \( B \). We launch \( \ell/2 \)-length random walks from each vertex in \( A \cup B \). The average lower bound on the dot product suffices to get a lower bound on the probability of getting a \( K_{25,25} \)-minor, which contains a \( K_5 \)-minor.

For the second problem, it turns out that the weaker bound of \( \|p_{v,\ell}\|_2 = \Omega(n^{-\delta}\|p_{v,\ell/2}\|_2) \) suffices. We could try to search for some value of \( \ell \) where this happens. If there was no (small) value of \( \ell \) where this bound held, then it suggest that \( \|p_{v,\delta}\|_2 \) is extremely small (say \( \Theta(1/n) \)).

This kind of reasoning is detailed more in the next subsection.

The third problem requires bounds on the variance, or higher norms, of \( p_{v,\ell/2} \). Unfortunately, there appears be no handle on these. At a high level, our idea is to truncate \( p_{v,\ell/2} \) by ignoring large entries. This truncated vector is not a probability vector any more, but we can hope to redo the analysis for such vectors.

Now for the fourth problem. Naturally, if the vertices \( v_1, \ldots, v_5 \) are close to each other, we do not expect to get a minor by connecting them. Suppose they were sufficiently “spread out”, One could hope that the paths connecting the \( v_i, v_j \) pairs would only intersect “near” the \( v_i \). The portion of the paths nears the \( v_i \)'s could be contracted to get a \( K_5 \)-minor. We can roughly quantify how far the \( v_i \)'s will be by the variance of \( p_{v,\ell/2} \). Thus, the third and fourth problem are coupled.

### 2.2 \( R \)-returning walks

The main technical contribution of our work is in defining \( R \)-returning walks. These are walks that periodically return to a given set \( R \) of vertices. A careful analysis of these walks provides to tools to handle the various problems discussed above.

Fix \( \ell \) as before. Formally, an \( R \)-returning walk of length \( j\ell \) (for \( j \in \mathbb{N} \)) is a walk that encounters \( R \) at every \( i\ell \) step \( \forall i \in [j] \). While random walk distributions can have poor variance, we can carefully choose \( R \) to ensure that the distribution of \( R \)-returning walks is well-behaved. We will quantify this as approximate “support uniformity” (being approximatedly uniform on the support).

In the leaky case, there is some (large) set \( R \), such that \( \forall s \in R, \|p_{s,\ell/2}\|_2^2 \leq 1/n^\alpha \). Let \( p_{[R],s,\ell} \) be the random walk distribution restricted to \( R \). Suppose for some \( s \in R, \|p_{[R],s,\ell}\|_2^2 \geq 1/n^\alpha+\delta \). Observe that each entry in \( p_{[R],s,\ell} \) is \( p_{s,\ell/2} \cdot p_{v,\ell/2} \) for \( s, v \in R \). By Cauchy-Schwarz, this is at most \( 1/n^\alpha \). For any distribution \( \nu \), the condition \( \|\nu\|_2^2 = \|\nu\|_\infty \) is equivalent to support uniformity. Thus, \( p_{[R],s,\ell} \) is approximately support uniform, up to \( n^\delta \) deviations. The math discussed in the
previous section goes through for any such $s$. In other words, if the random walk algorithm started from $s$, it succeeds in finding a $K_5$ minor.

Suppose only a negligible fraction of vertices satisfied this condition, and so our algorithm would not actually find such a vertex. Let us remove all these vertices from $R$ (abusing notation, let $R$ be the resulting set). Now, $\forall s \in R$, $\|p_{[R],s,\ell}\|_2^2 \leq 1/n^{\alpha+\delta}$. So, the bound on the $l_2$-norm has fallen by an $n^\delta$ factor. What does $p_{[R],s,\ell} \cdot p_{[R],v,\ell}$ signify? This is the probability of a $2\ell$-length random walk starting from $s$, ending at $v$, and encountering $R$ at the $\ell$th step. This is an $R$-returning walk of length $2\ell$. Let $q_{[R],s,2\ell}$ denote the vector of $R$-returning walk probabilities. Suppose for some $s$, $\|q_{[R],s,2\ell}\|_2^2 \geq 1/n^{\alpha+2\delta}$. By Cauchy-Schwarz, $\|q_{[R],s,2\ell}\|_\infty \leq 1/n^{\alpha+\delta}$, implying that $q_{[R],s,2\ell}$ is approximately support uniform. Again, the math of the previous section goes through for such an $s$.

We remove all vertices that have this property, and end up with $R$ such that $\forall s \in R$, $\|q_{[R],s,2\ell}\|_2^2 \leq 1/n^{\alpha+2\delta}$. Observe that $q_{[R],s,2\ell} \cdot q_{[R],v,2\ell}$ is a probability of a $4\ell$ $R$-returning walk. We then iterate this argument.

In general, this argument goes through phases. In the $i$th phase, we find $s \in R$ that satisfy $\|q_{[R],s,2\ell}\|_2^2 \geq 1/n^{\alpha+i\delta}$. We show that the random walk procedure of the previous section (with some modifications) finds a $K_5$-minor starting from such vertices. We remove all such vertices from $R$, increment $i$ and continue the argument. The vertices removed at the $i$th phase are called the $i$th stratum, and we refer to this entire process as stratification. Intuitively, for vertices in the $i$th stratum, the $R$-returning (for the setting of $R$ at that phase) walk probabilities roughly form a uniform distribution of support $n^{\alpha+i\delta}$. Thus, for vertices in higher strata, the random walks are spreading to larger sets.

There is a major problem. The $q$ vectors are not distributions, and the vast majority of walks are not $R$-returning. Indeed, the reduction in norm as we increase strata might simply be an artifact of the lower probability of a longer $R$-returning walk (note that the walks lengths are increasing exponentially in the phase number). We prove a spectral lemma asserting that this is not the case. As long as $R$ is sufficiently large, the probabilities of $R$-returning walks are sufficiently high. Unfortunately, these probabilities (must) decrease exponentially in the number of returns. In the $i$th phase, the walk length is $2^i\ell$ and it must return to $R$ $2^i$ times. Here is where the $n^\delta$ decay in $l_2$-norm condition saves us. After $1/\delta$ phases, the $\|q_{[R],s,2\ell}\|_2^2$ is basically $1/n$. The spectral lemma tells us that if $R$ is still large, the probability that a $2^{1/\delta}\ell$ length walk is $R$-returning is sufficiently large. Thus, the norm cannot decrease, and almost all vertices end up in the very next stratum. If $R$ was small, then there is an earlier stratum containing $\Omega(\delta \varepsilon n)$ vertices. Regardless of the case, there exists a $i \leq 1/\delta + O(1)$ such that the $i$th stratum contains $\Omega(\delta \varepsilon n)$ vertices. For all these vertices, the random walk algorithm to find minors succeeds with non-trivial probability.

### 2.3 The trapped case: local partitioning to the rescue

In this case, for almost all vertices $\|p_{s,\ell}\|_2^2 \geq 1/n^\alpha$. The proofs of the (contrapositive of the) Cheeger inequality basically imply the existence of a set of low conductance cut $P_s$ “around” $s$. By local partitioning methods such as those of Spielman-Teng and Anderson-Chung-Lang [ST12, ACL06], we can actually find $P_s$ in roughly $n^\alpha$ time. We expect our graph to basically decompose into $O(n^\alpha)$ sized components with few edges between them. Our algorithm can simply find these pieces $P_s$ and run a planarity test on them. We refer to this as the local search procedure.

While the intuition is correct, the analysis is difficult. The main problem is that actual parti-
tioning of the graph (into small components connected by low conductance cuts) is fundamentally iterative. It starts by finding a low conductance set $P_s$ in $\overline{P_s}$, then $P_{s_2}$ in $\overline{P_{s_1}} \cup \overline{P_s}$, and so on. In general, this requires conditions on the random walk behavior inside $\bigcup_{j<i} P_s$. On the other hand, our algorithm and the trapped case condition only refer to random walk behavior in all of $G$. Furthermore, $\bigcup_{j<i} P_s$ can be as small as $\Theta(\varepsilon n)$, and so we do expect the random walk behavior to be quite different.

The GR bipartiteness analysis surmounts this problem and performs such a decomposition, but their parameters do not work for us. Starting from a source vertex $s$, their analysis discovers $P_s$ such that probabilities of reaching any vertex in $P_s$ (from $s$) is roughly uniform and smaller than $1/\sqrt{n}$. On the other hand, we would like to discover all of $P_s$ in $n^{O(\delta)}$ time so that we can run a full planarity test.

We employ a collection of tools, and use the methods of Kale-Peres-Seshadhri to analyze “projected” Markov Chains [KPS13]. In the analysis above, we have some set $S$ ($\bigcup_{j<i} P_s$) and want to find a low conductance set $P$ completely contained in $S$. Moreover, we wish to discover $P$ using random walks in $G$. We construct a Markov chain, $M_S$, with vertex set $S$, and include new transitions that correspond to walks in $G$ whose intermediate vertices are not in $S$. Each such transition has an associated “cost,” corresponding to the actual length in $G$. (GR also have a similar idea, although their Markov chain introduces extra vertices to track the length of the walk in $G$. This makes the analysis somewhat unwieldy, since low conductance cuts in $M_S$ may include these extra vertices.)

Using bounds on the return time of random walks, we have relationships between the average length of a walk in $G$ whose endpoints are in $S$ and the corresponding length when “projected” to $M_S$. On average, an $\ell$-length walk in $G$ with endpoints in $S$ corresponds to an $\ell|S|/n$-length walk in $M_S$. Roughly speaking, we hope that for many vertices $s$, an $\ell|S|/n$-length walk in $M_S$ is trapped in a set of size $n^\alpha$.

We employ the Lovász-Simonovits curve technique to produce a low conductance cut $P_s$ in $M_S$ [LS90]. We can guarantee that all vertices in $P_s$ are reachable with roughly $n^{-\alpha}$ probability from $s$ through $\ell|S|/n$-length random walks in $M_S$. Using the average length correspondence between walks in $M_S$ to $G$, we can make a similar statement in $G$ - albeit with a longer length. We basically iterate over this entire argument to produce the decomposition into low conductance pieces.

In our analysis, we use the stratification itself to (implicitly) distinguish between the leaky and trapped case. Stratification peels the graph into $1/\delta + O(1)$ strata. If a vertex $s$ lies in a stratum numbered at least some fixed constant $b$, we can show that the algorithm finds a $K_r$-minor with $s$ as the starting vertex. Thus, if at least (say) $n^{1-\delta}$ vertices lie in stratum $b$ or higher, we are done. If $s$ is in a low strata, we have a lower bound on the random walks norm. This allows for local partitioning around $s$.

### 3 The algorithm

We are given a bounded degree graph $G = (V,E)$, with max degree $d$. We assume that $V = [n]$. We follow the standard adjacency list model of Goldreich-Ron for (random) access to the graph. This model allows an algorithm to sample u.a.r. vertices and perform edge queries. Given a pair $(v,i) \in [n] \times [d]$, the output of an edge query is the $i$th neighbor of $v$ according to the adjacency list ordering. If the degree of $v$ is smaller than $i$, the output is $\perp$. 

7
In the algorithm, the phrase “random walk” refers to a lazy random walk on $G$. Given a current vertex $v$, with probability $1/2$, the walk remains at $v$. With probability $1/2$, the procedure generates u.a.r. $i \in [d]$. It performs the edge query for $(v, i)$. If the output is $\perp$, the walk remains at $v$, otherwise the walk visits the output vertex. This is a symmetric, ergodic Markov chain with a uniform stationary distribution.

Our main procedure $\text{FindMinor}(G, \varepsilon, H)$, tries to find a $H$-minor in $G$. We prove that it succeeds with high probability if $G$ is $\varepsilon$-far from being $H$-minor free. There are three subroutines:

- **LocalSearch($s$):** This procedure perform a small number of short random walks to find the piece described in §2.3. This produces a small subgraph of $G$, where an exact $H$-minor finding algorithm is used.
- **FindPath($u, v, k, i$):** This procedure tries to find a path from $u$ to $v$. The parameter $i$ decides the length of the walk, and the procedure performs $k$ walks from $u$ and $v$. If any pair of these walks collide, this path is output.
- **FindBiclique($s$):** This is the main procedure mostly as described in §2.1. It attempts to find a sufficiently large biclique minor. First, it generates seed sets $A$ and $B$ by performing random walks from $s$. Then, it calls $\text{FindPath}$ on all pairs in $A \times B$.

We fix a collection of parameters.
- $\delta$: An arbitrarily small constant.
- $r$: The number of vertices in $H$.
- $\ell$: The random walk length. This will be $n^{5\delta}$.
- $\varepsilon_{\text{CUTOFF}}$: $\varepsilon_{\text{CUTOFF}} = n^{-\exp(2/\delta)}$. If $\varepsilon < \varepsilon_{\text{CUTOFF}}$, the algorithm just queries the whole graph.
- $\text{KKR}(F, H)$: This refers to an exact $H$-minor finding process (in $F$). For concreteness, we use the quadratic time procedure of Kawarabayashi-Kobayashi-Reed [KKR12].

**FindMinor($G, \varepsilon, H$)**
1. If $\varepsilon < \varepsilon_{\text{CUTOFF}}$, query all of $G$, and output $\text{KKR}(G, H)$
2. Else
   (a) Repeat $\varepsilon^{-2} n^{35\delta r^4}$ times:
      i. Pick u.a.r $s \in V$
      ii. Call LocalSearch($s$) and FindBiclique($s$).

**LocalSearch($s$)**
1. Initialize set $B = \emptyset$.
2. For $h = 1, \ldots, n^{7\delta r^4}$:
   (a) Perform $\varepsilon^{-1} n^{30\delta r^4}$ independent random walks of length $h$ from $s$. Add all destination vertices to $B$.
3. Determine $G[B]$, the subgraph induced by $B$.
4. Run $\text{KKR}(G[B], H)$. If it returns an $H$-minor, output that and terminate.
**FindBiclique(s)**

1. For \( i = 5r^4, \ldots, 1/\delta + 4 \):
   a. Perform \( 2r^2 \) independent random walks of length \( 2^{i+1}\ell \) from \( s \). Let the destinations of the first \( r^2 \) walks be multiset \( A \), and the destinations of the remaining walks be \( B \).
   b. For each \( a \in A, b \in B \):
      i. Run \( \text{FindPath}(a, b, n^{\delta(i+18)/2}, i) \)
   c. If all calls to \( \text{FindPath} \) return a path, then let the collection of paths be the subgraph \( F \). Run \( \text{KRR}(F, H) \). If it returns an \( H \)-minor, output that and terminate.

**FindPath(u, v, k, i)**

1. Perform \( k \) random walks of length \( 2^i \ell \) from \( u \) and \( v \).
2. If a walk from \( u \) and \( v \) terminate at the same vertex, return these paths. (Otherwise, return nothing.)

**Theorem 3.1.** If \( G \) is \( \varepsilon \)-far from being \( H \)-minor free, then \( \text{FindMinor}(G, \varepsilon, H) \) finds an \( H \)-minor of \( G \) with probability at least \( 2/3 \). Furthermore, \( \text{FindMinor} \) has a running time of \( dn^{1/2+O(\delta r^4)} + d\varepsilon^{-2}\exp(2\delta)/\delta \).

The query complexity is fairly easy to compute. The total queries made in the \( \text{LocalSearch} \) calls is \( dn^{O(\delta r^4)} \). The main work happens in the calls of \( \text{FindPath} \), within \( \text{FindBiclique} \). Observe that \( k \) is set to \( n^{\delta(i+18)/2} \), where \( i \leq 1/\delta + 4 \). This leads to the \( \sqrt{n} \) in the final complexity. (In general, a setting of \( \delta < 1/\log(\varepsilon^{-1} \log \log n) \) suffices for an \( n^{1/2+o(1)} \) running time.)

**Outline:** There are a number of moving parts in the proof, which we relegate to their own subsections. We first develop the notion of \( R \)-returning walks and the stratification process, given in §4. In §5, we use these techniques to prove that \( \text{FindBiclique} \) discovers a sufficiently large biclique-minor in the leaky case. In §6, we prove a local partitioning lemma that will be used to handle the trapped case. Finally, in §7, we put the tools together to complete the proof of Theorem 3.1.

## 4 Returning walks and stratification

We introduce the concept of \( R \)-returning random walks for any \( R \subseteq V \). These definitions are with respect to a fixed length \( \ell \).

**Definition 4.1.** For any set of vertices \( R, s \in R, u \in R, \) and \( i \in \mathbb{N} \), we define the \( R \)-returning probability as follows. We denote by \( q^{(i)}_{[R],s}(u) \) the probability that a \( 2^i \ell \)-length random walk from \( s \) ends at \( u \), and encounters a vertex in \( S \) at every \( j \ell \)th step, for all \( 1 \leq j \leq 2^i \). The \( R \)-returning probability vector, denoted by \( q^{(i)}_{[R],s} \), is the \( |R| \)-dimensional vector of returning probabilities.

**Proposition 4.2.** \( q^{(i+1)}_{[R],s}(u) = q^{(i)}_{[R],s} \cdot q^{(i)}_{[R],u} \)

**Proof.** We use the symmetry of (returning) random walks in \( G \).

\[
q^{(i+1)}_{[R],s}(u) = \sum_{w \in S} q^{(i)}_{[R],s}(w) q^{(i)}_{[R],u}(w) = \sum_{w \in R} q^{(u)}_{[R],s}(w) q^{(i)}_{[R],u}(w) = q^{(i)}_{[R],s} \cdot q^{(i)}_{[R],u}
\]

\[\square\]
Let $M$ be the transition matrix of the lazy random walk on $G$. Let $\mathbb{P}_R$ be the $n \times |R|$ matrix on $R$, where each column is the unit vector for some $s \in R$. For any set $U$, we use $1_U$ for the indicator vector on $U$. If no subscript is given, it is the all ones vector, for the appropriate dimension.

**Proposition 4.3.** $q_{[R],s}^{(i)} = (\mathbb{P}_R^T M^{\ell/2} \mathbb{P}_R)^{2^i} 1_s$

Now for a critical lemma. We can lower bound the total probability of an $R$-returning random walk. If $R$ contains at least a $\beta$-fraction of vertices, the average $R$-returning walk probability, for $t$ returns, is at least $\beta^t$.

**Lemma 4.4.** $|R|^{-1} \sum_{s \in R} \|q_{[R],s}^{(i)}\|_1 \geq (|R|/n)^{2^i}$

**Proof.** We will express $\sum_{s \in R} \|q_{[R],s}^{(i)}\|_1 = 1^T (\mathbb{P}_R^T M^{\ell/2} \mathbb{P}_R)^{2^i} 1$. Let us first prove the lemma for $i = 0$. Observe that $\sum_{s \in R} \|q_{[R],s}^{(0)}\|_1 = 1^T M^{\ell/2} 1 = \|(M^{\ell/2})^T (M^{\ell/2} 1)\|_2 = \|M^{\ell/2} 1\|_2^2$. Since $M^{\ell/2}$ is a stochastic matrix, $\|M^{\ell/2} 1\|_1 = \|1\|_1 = |R|$. By a standard norm inequality, $\|M^{\ell/2} 1\|_2^2 \geq |R|^2/n$. This completes the proof for $i = 0$.

Let $N = \mathbb{P}_R^T M^{\ell/2} \mathbb{P}_R$, which is a symmetric matrix. We have just proven that $1^T N 1 \geq |R|^2/n$. Let the eigenvalues of $N$ be $1 \geq \lambda_1 \geq \lambda_2 \ldots \lambda_{|R|}$, with corresponding eigenvectors $u_1, u_2, \ldots, u_s$. We can express $1 = \sum_{k \leq |R|} \alpha_k u_k$, where $\sum_k \alpha_k^2 = |R|$. Observe that $N^{2^i} 1 = \sum_{k \leq |R|} \alpha_k \lambda_k^{2^i} u_k$.

Let $\mu_k = \alpha_k^2 / \sum_j \alpha_j^2$, noting that $\sum_k \mu_k = 1$. We apply Jensen’s inequality below.

$$
\frac{1^T N 1}{|R|} = \sum_{k \leq |R|} \alpha_k \lambda_k^{2^i} = \sum_k \mu_k \lambda_k^{2^i} \geq (\sum_k \mu_k \lambda_k)^{2^i}
$$

For $i = 0$, we already proved that $1^T N 1/|R| = \sum_k \mu_k \lambda_k \geq |R|/n$. We plug this bound to complete the proof for general $i$. 

**4.1 Stratification**

Stratification results in a collection of disjoint sets of vertices denoted by $S_0, S_1, \ldots$ which are called *strata*. The corresponding residue sets denoted by $R_0, R_1, \ldots$. The zeroth residue $R_0$ is initialized before stratification and subsequent residues are defined by the recurrence $R_t = R_0 \setminus \bigcup_{j<i} S_j$. The definitions and claims may seem technical, and the proofs are mostly norm manipulations. But these provide the tools to analyze our main algorithm.

**Definition 4.5.** Suppose $R_i$ has been constructed. A vertex $s \in R_i$ is placed in $S_i$ if $\|q_{[R_i],s}^{(i+1)}\|_2^2 \geq 1/n^{\delta i}$.

We have an upper bound for the length of $R_i$-returning walk vectors.

**Claim 4.6.** For all $s \in R_i$ and $1 \leq j \leq i$, $\|q_{[R_i],s}^{(j)}\|_2^2 \leq 1/n^{\delta(j-1)}$.

**Proof.** Suppose $\exists j \leq i, \|q_{[R_i],s}^{(j)}\|_2^2 > 1/n^{\delta(j-1)}$. By assumption, $s \in R_i \subseteq R_{j-1}$. An $R_i$-returning walk from $s$ is also an $R_{j-1}$-returning walk. Thus, every entry of $q_{[R_{j-1}],s}^{(j)}$ is at least that of $q_{[R_i],s}^{(j)}$. So $\|q_{[R_{j-1}],s}^{(j)}\|_2^2 \geq \|q_{[R_i],s}^{(j)}\|_2^2 > 1/n^{\delta(j-1)}$. This implies that $s \in S_{j-1}$ or an earlier stratum, contradicting the assumption that $s \in R_i$. 

10
We prove an $\ell_{\infty}$ bound on the returning probability vectors. Note that we allow $j$ to be $i + 1$ in the following bound.

**Claim 4.7.** For all $s \in R_i$ and $2 \leq j \leq i + 1$, $||q^{(j)}_{[R_i],s}||_{\infty} \leq 1/n^\delta(j-2)$.

**Proof.** By Prop. 4.2, for any $v \in R_i$, $q^{(j)}_{[R_i],s}(v) = q^{(j-1)}_{[R_i],s} \cdot q^{(j-1)}_{[R_i],v}$. Note that $1 \leq j-1 \leq i$. By Cauchy-Schwartz and Claim 4.6, $q^{(j)}_{[R_i],s}(v) \leq 1/n^{\delta(j-2)}$. □

As a consequence of these bounds, we are able to bound the amount of probability mass retained by $R_i$-returning walks.

** Claim 4.8.** For all $s \in S_i$, $||q^{(i+1)}_{[R_i],s}||_1 \geq n^{-\delta}$.

**Proof.** Since $s \in S_i$, $||q^{(i+1)}_{[R_i],s}||^2_2 \geq n^{-\delta}$, and by Claim 4.7, $||q^{(i+1)}_{[R_i],s}||_{\infty} \leq n^{-\delta(i-1)}$. Since, $||q^{(i+1)}_{[R_i],s}||^2_2 \leq ||q^{(i+1)}_{[R_i],s}||_1 ||q^{(i+1)}_{[R_i],s}||_{\infty}$, we conclude $||q^{(i+1)}_{[R_i],s}||_1 \geq n^{-\delta} n^{\delta(i-1)} = n^{-\delta}$. □

We prove that most vertices lie in “early” strata.

**Lemma 4.9.** Suppose $\varepsilon \geq \varepsilon_{\text{CUTOFF}}$. At most $\varepsilon n / \log n$ vertices are in $R_{1/\delta+3}$.

**Proof.** We prove by contradiction. Suppose that $R_{1/\delta+3}$ has at least $\varepsilon n / \log n$ vertices. The previous residue, $R_{1/\delta+2}$, is only bigger and thus $|R_{1/\delta+2}| \geq \varepsilon n / \log n$ as well. By Lemma 4.4,

$$|R_{1/\delta+2}^{-1} \sum_{s \in R_{1/\delta+2}} ||q^{(1/\delta+3)}_{[R_{1/\delta+2}],s}||_1 | \geq \left( \frac{\varepsilon}{\log n} \right)^{2^{1/\delta+4}}.$$  

(1)

By averaging and a standard $l_1$-$l_2$ norm inequality,

$$||q^{(1/\delta+3)}_{[R_{1/\delta+2}],s}||^2_2 \geq n^{-1} \left( \frac{\varepsilon}{\log n} \right)^{2^{1/\delta+4}}.$$  

(2)

By assumption, $\varepsilon \geq \varepsilon_{\text{CUTOFF}} \geq n^{-\delta / \exp(1/\delta)}$. For sufficiently small $\delta$, $\delta / \exp(1/\delta) < 2\delta / 2^{1/\delta+4}$. Thus, $\varepsilon \geq (\log n)n^{-2\delta / (2^{1/\delta+4})}$. Plugging into the RHS of the previous equation, $||q^{(1/\delta+3)}_{[R_{1/\delta+2}],s}||^2_2 \geq 1/n^{1+2\delta} = 1/n^{\delta(1/\delta+2)}$. This implies that $v \in S_{1/\delta+2}$, a contradiction. □

### 4.2 The correlation lemma

The following lemma is an important tool in our analysis. Here is an intuitive explanation. Fix some $s \in S_i$. By Prop. 4.2, the probability $q^{(i+1)}_{[R_i],s}(v)$ is the correlation between the vectors $q^{(i)}_{[R_i],s}$ and $q^{(i)}_{[R_i],v}$. If many of these probabilities are large, then there are many $v$ such that $q^{(i)}_{[R_i],v}$ is correlated with $q^{(i)}_{[R_i],s}$. We then expect many of these vectors to be correlated among themselves.

**Definition 4.10.** For $s \in R_i$, the distribution $D_{s,i}$ has support $R_i$, and the probability of $u \in R_i$ is $q^{(i+1)}_{[R_i],s}(v) = q^{(i+1)}_{[R_i],s}(v)/||q^{(i+1)}_{[R_i],s}||_1$. 

11
Lemma 4.11. Fix arbitrary \( s \in R_i \).

\[
E_{u_1,u_2 \sim \mathcal{D}_s}[q^{(i)}_{[R_i],u_1} \cdot q^{(i)}_{[R_i],u_2}] \geq \frac{1}{\|q^{(i+1)}_{[R_i],s}\|^2} \cdot \frac{1}{\|q^{(i)}_{[R_i],s}\|^2} \cdot \frac{1}{\|q^{(i)}_{[R_i],s}\|^2} \cdot \frac{1}{\|q^{(i)}_{[R_i],s}\|^2}
\]

Proof. By Lemma 4.11, the LHS is at least \( \frac{1}{\|q^{(i+1)}_{[R_i],s}\|^2} \cdot \frac{1}{\|q^{(i)}_{[R_i],s}\|^2} \). Note that \( \|q^{(i+1)}_{[R_i],s}\|_2 \leq 1 \). By Definition 4.5, \( \|q^{(i+1)}_{[R_i],s}\|^2 \geq 1/n^\delta i \). Since \( s \in S_i \subseteq R_i \), by Claim 4.6, \( \|q^{(i)}_{[R_i],s}\|_2 \leq 1/n^\delta (i-1) \).
5 Analysis of FindBiclique

This is the central theorem of our analysis. It shows that the FindBiclique(s) procedure discovers a \( K_{r^2, r^2} \) minor with non-trivial probability when \( s \) is in a sufficiently high stratum.

**Theorem 5.1.** Suppose \( s \in S_i \), for \( 5n^4 \leq i \leq 1/\delta + 3 \). The probability that the paths discovered in FindBiclique(s) contain a \( K_{r^2, r^2} \) minor is at least \( n^{-45r^4} \).

Theorem 5.1 is proved in §5.5. Towards the proof, we will need multiple tools. In §5.1, we perform a standard calculation to bound the success probability of FindPath. In §5.2, we use this bound to show that the sets \( A \) and \( B \) sampled by FindBiclique are successfully connected by paths as discovered by FindPath. In §5.3, we argue that the intersections of these paths is “well-behaved” enough to induce a \( K_{r^2, r^2} \) minor.

We note that the \( \sqrt{n} \) in the final running time comes from the calls to FindPath in FindBiclique.

5.1 The procedure FindPath

For convenience, we reproduce the procedure FindPath. It is a relatively straightforward application of a birthday paradox argument for bidirectional path finding.

\[
\text{FindPath}(u, v, k, i)
\]

1. Perform \( k \) random walks of length \( 2^i \ell \) from \( u \) and \( v \).
2. If a walk from \( u \) and \( v \) terminate at the same vertex, return these paths.

**Lemma 5.2.** Let \( c \) be a sufficiently large constant. Consider \( u, v \in R_i \). Suppose there exist \( \alpha \leq \beta \) such that \( \max(||q_{[R_i], u}^{(i)}||_2, ||q_{[R_i], v}^{(i)}||_2) \leq 1/n^\alpha \) and \( q_{[R_i], u}^{(i)} \cdot q_{[R_i], v}^{(i)} \geq 1/2n^\beta \). Then, with \( k \geq cn^{\beta/2+4(\beta-\alpha)} \), FindPath\((u, v, k, i)\) returns an \( R_i \)-returning path of length \( 2^i \ell \) with probability \( \geq 2/3 \).

**Proof.** First, define \( W = \{ w | q_{[R_i], u}^{(i)}(w)/q_{[R_i], v}^{(i)}(w) \in [1/(8n^{\beta-\alpha}), 8n^{\beta-\alpha}] \} \).

\[
\sum_{w \notin W} q_{[R_i], u}^{(i)}(w)q_{[R_i], v}^{(i)}(w) \leq (8n^{\beta-\alpha})^{-1} \sum_{w \notin W} \max(q_{[R_i], u}^{(i)}(w), q_{[R_i], v}^{(i)}(w))^2 \leq (8n^{\beta-\alpha})^{-1}(||q_{[R_i], u}^{(i)}||_2^2 + ||q_{[R_i], v}^{(i)}||_2^2) \leq 1/4n^\beta
\]

Therefore, \( \sum_{w \in W} q_{[R_i], u}^{(i)}(w)q_{[R_i], v}^{(i)}(w) \geq 1/2n^\beta \).

For \( a, b \leq k \), let \( X_{a,b} \) be the indicator for the following event: the \( a \)th \( 2^i \ell \)-length random walk from \( u \) is an \( R_i \)-returning walk that ends at some \( w \in W \), and the \( b \)th random walk from \( v \) is also \( R_i \)-returning, ending at the same \( w \). Let \( X = \sum_{a,b \leq k} X_{a,b} \). Observe that the probability that FindPath\((u, v, k, i)\) returns a path is at least \( \Pr[X > 0] \).

We can bound \( \mathbb{E}[\sum_{a,b \leq k} X_{a,b}] = k^2 \sum_{w \in W} q_{[R_i], u}^{(i)}(w)q_{[R_i], v}^{(i)}(w) \geq k^2/4n^\beta \geq (c^2/4)n^{4(\beta-\alpha)} \). Let us now bound the variance. First, let us expand out the expected square.

\[
\mathbb{E}[(\sum_{a,b} X_{a,b})^2] = \sum_{a,b} \mathbb{E}[X_{a,b}^2] + 2 \sum_{a \neq a', b} \mathbb{E}[X_{a,b}X_{a', b}] + 2 \sum_{a \neq b, a' \neq b'} \mathbb{E}[X_{a,b}X_{a', b'}] + 2 \sum_{a \neq a', b \neq b'} \mathbb{E}[X_{a,b}X_{a', b'}]
\]

(13)
Observe that $X_{a,b}^2 = X_{a,b}$. Furthermore, for $a \neq a', b \neq b'$, by independence of the walks, $\mathbf{E}[X_{a,b}X_{a',b'}] = \mathbf{E}[X_{a,b}]\mathbf{E}[X_{a',b'}]$. (This term will cancel out in the variance.) By symmetry, $\sum_{a \neq a', b} \mathbf{E}[X_{a,b}X_{a',b}] = k^3 \mathbf{E}[X_{1,1}X_{2,1}]$ (and analogously for the third term in (13)). Plugging these in and expanding out the $\mathbf{E}[X]^2$,

$$\text{var}[X] \leq \mathbf{E}[X] + 2k^3 \mathbf{E}[X_{1,1}X_{2,1}] + 2k^3 \mathbf{E}[X_{1,1}X_{1,2}]$$

Note that $X_{1,1}X_{2,1} = 1$ when the first and second walks from $u$ end at the same vertex where the first walk from $v$ ends. Thus, $\mathbf{E}[X_{1,1}X_{2,1}] = \sum_{w \in W} q_{[R_i],u}(w)q_{[R_i],v}(w)$. Since $w \in W$, $q_{[R_i],v}(w) \leq 8n^{\beta-\alpha}q_{[R_i],u}(w)$. Plugging this bound in,

$$2k^3 \mathbf{E}[X_{1,1}X_{2,1}] \leq 16k^3n^{\beta-\alpha} \sum_{w \in W} q_{[R_i],u}(w)^3 \leq 16k^3n^{\beta-\alpha} \left[ \sum_{w \in W} q_{[R_i],u}(w)^2 \right]^{3/2} \leq 64n^{2(\beta-\alpha)} \left[ \sum_{w \in W} q_{[R_i],u}(w)^2 \right]^{3/2} \leq (\mathbf{E}[X]^{1/2}/(c/128))(\mathbf{E}[X]^{3/2}) = \mathbf{E}[X]^2/(c/128)$$

(For the last line, we use the bound $\mathbf{E}[X] \geq (c^2/4)n^{4(\beta-\alpha)}$. We get an identical bound for $2k^3 \mathbf{E}[X_{1,1}X_{1,2}]$. Putting it all together, we can prove that $\text{var}[X] \leq 4\mathbf{E}[X]^2/c'$. An application of Chebyshev proves that $\Pr[X > 0] > 2/3$.)

### 5.2 The procedure FindBiclique

For convenience, we reproduce FindBiclique.

**FindBiclique(s)**

1. For $i = 5r^4, \ldots, 1/\delta + 4$:
   
   (a) Perform $2r^2$ independent random walks of length $2^{i+1}\ell$ from $s$. Let the destinations of the first $r^2$ walks be multiset $A$, and the destinations of the remaining walks be $B$.

   (b) For each $a \in A$, $b \in B$:
      
      i. Run $\text{FindPath}(a, b, n^{\delta(i+18)/2}, i)$

   (c) If all calls to $\text{FindPath}$ return a path, then let the collection of paths be the subgraph $F$. Run $\text{KKR}(F, H)$. If it returns an $H$-minor, output that and terminate.

**Lemma 5.3.** Suppose $s \in S_i$, for some $i \leq 1/\delta + 4$. Condition on the event that $A, B \subseteq R_i$, during the $i$th iteration in $\text{FindBiclique}(s)$. With probability $(4n^{2\delta})^{-r^4}$, the calls to $\text{FindPath}$ output paths from every $a \in A$ to every $b \in B$, where each path is an $R_i$-returning walk of length $2^{i+1}\ell$.

**Proof.** The probability that a $2^{i+1}\ell$-length random walk from $s$ ends at $u$ is at least $q_{[S_i],s}^{(i+1)}(u)$ $= \hat{q}_{[R_i],s}^{(i+1)}(u)\|q_{[R_i],s}^{(i+1)}\|_1$. In the rest of the proof, let $t = |A| = |B| = r^2$ denote the common size of the multisets $A$ and $B$. For any $a, b \in V$, let $\tau_{a,b}$ be the probability that $\text{FindPath}(a, b, n^{\delta(i+18)/2}, i)$
succeeds in finding an $R_i$-returning walk between $a$ and $b$ (of length $2^{i+1} \ell$). The probability of success for $\text{FindBiclique}(s)$ conditioned on $A, B \subseteq R_i$ is at least

$$
\sum_{A \in R_i^s} \sum_{B \in R_i^s} \prod_{a \in A} \prod_{b \in B} q_{[R_i],a}^{(i+1)}(a) q_{[R_i],b}^{(i+1)}(b) \tau_a b = \sum_{A \in R_i^s} \sum_{B \in R_i^s} \prod_{a \in A} \prod_{b \in B} q_{[R_i],a}^{(i+1)}(a) \left( \prod_{b \in B} q_{[R_i],b}^{(i+1)}(b) \right) \prod_{b \in B} \tau_a b 
$$

$$
= \sum_{B \in R_i^s} \left( \prod_{b \in B} q_{[R_i],b}^{(i+1)}(b) \right) \sum_{A \in R_i^s} \prod_{a \in A} q_{[R_i],a}^{(i+1)}(a) \left( \prod_{b \in B} \tau_a b \right)
$$

$$
= \sum_{B \in R_i^s} \prod_{b \in B} q_{[R_i],b}^{(i+1)}(b) \left( \sum_{a \in R_i} q_{[R_i],a}^{(i+1)}(a) \prod_{b \in B} \tau_a b \right)^t.
$$

Observe that $\prod_{b \in B} q_{[R_i],b}^{(i+1)}(b)$ is a probability distribution over $B$. By Jensen, we lower bound.

$$
\sum_{B \in R_i^s} \left( \prod_{b \in B} q_{[R_i],b}^{(i+1)}(b) \right) \left( \sum_{a \in R_i} q_{[R_i],a}^{(i+1)}(a) \prod_{b \in B} \tau_a b \right)^t \geq \sum_{B \in R_i^s} \left( \prod_{b \in B} q_{[R_i],b}^{(i+1)}(b) \right) \sum_{a \in R_i} q_{[R_i],a}^{(i+1)}(a) \prod_{b \in B} \tau_a b
$$

We manipulate and expand further.

$$
\left[ \sum_{a \in R_i} \sum_{B \in R_i^s} q_{[R_i],a}^{(i+1)}(a) \prod_{b \in B} q_{[R_i],b}^{(i+1)}(b) \prod_{b \in B} \tau_a b \right]^t
$$

$$
= \left[ \sum_{a \in R_i} q_{[R_i],a}^{(i+1)}(a) \sum_{B \in R_i^s} \prod_{b \in B} q_{[R_i],b}^{(i+1)}(b) \tau_a b \right]^t
$$

$$
= \left[ \sum_{a \in R_i} q_{[R_i],a}^{(i+1)}(a) \left( \sum_{b \in R_i} q_{[R_i],b}^{(i+1)}(b) \tau_a b \right)^t \right]^2
$$

$$
\geq \left[ \sum_{a \in R_i} q_{[R_i],a}^{(i+1)}(a) \sum_{b \in R_i} q_{[R_i],b}^{(i+1)}(b) \tau_a b \right]^2
$$

$$
= \left[ \mathbb{E}_{a,b \sim \mathcal{D}, s} [\tau_a b] \right]^2.
$$

Towards lower bounding $\tau_a b$, we first lower bound $q_{[R_i],a}^{(i)} \cdot q_{[R_i],b}^{(i)}$. By Lemma 4.12, $\mathbb{E}_{a,b} [q_{[R_i],a}^{(i)} \cdot q_{[R_i],b}^{(i)}] \geq 1/n^\delta(i+1)$. Applying Cauchy-Schwartz, $q_{[R_i],a}^{(i)} \cdot q_{[R_i],b}^{(i)} \leq 1/n^\delta(i-1)$. Let $p$ be the probability (over $a, b$) that $q_{[R_i],a}^{(i)} \cdot q_{[R_i],b}^{(i)} \geq 1/2n^\delta(i+1)$.

$$
1/n^\delta(i+1) \leq \mathbb{E}_{a,b} [q_{[R_i],a}^{(i)} \cdot q_{[R_i],b}^{(i)}] \leq (1-p)/2n^\delta(i+1) + p/n^\delta(i-1)
$$

Thus, $p \geq 1/2n^{2\delta}$.

By Claim 4.6, for every $a \in R_i$, $\|q_{[R_i],a}^{(i)}\|_2^2 \leq 1/n^\delta(i-1)$ (similarly for $b \in R_i$). Suppose $q_{[R_i],a}^{(i)} \cdot q_{[R_i],b}^{(i)} \geq 1/2n^\delta(i+1)$. Let us apply Lemma 5.2, with $\alpha = \delta(i-1)$ and $\beta = \delta(i+1)$. The number of paths taken in $\text{FindPath}$ (the value $k$) is $n^{\delta(i+18)/2}$. Note that $\delta(i+18)/2 > \delta(i+1)/2 + 8\delta =$
We will define some bad vertex may appear multiple times in \(A\). Therefore, equality refers to vertex at the same index in sequences, rather than sets, since the order in which the path is constructed is relevant. For any paths, pick the lexicographically least.

\[
\exists \quad \tau = 2^{i-1}\ell.
\]

1. \(\exists a, b, c \in A \cup B, c \neq a, b, \text{ such that } W_a \cap P_{a,b} \neq \emptyset.\)
2. \(\exists a, b, b' \text{ (all distinct) such that } \exists W \in W_a^b \text{ where } W(\geq \tau) \cap P_{a,b'} \neq \emptyset. (Or, } \exists a, a' \in A, b \in B, \text{ all distinct, such that } \exists W \in W_a^b \text{ where } W(\geq \tau) \cap P_{a',b} \neq \emptyset.\)
3. \(\exists a, b, W_a \in W_a^b, W_b \in W_b^b \text{ such that } W_a, W_b \text{ end at the same vertex and } \exists t_1, t_2 \text{ such that } \min(t_1, t_2) \leq \tau \text{ and } W_a(t_1) = W_b(t_2).\)

For clarity, let us express the above bad events in plain English. Note that \(\tau\) is the index of the midpoint of the walks, so it splits walks into halves.

1. A walk from \(c \in A \cup B\) intersects \(P_{a,b}\), where \(c \neq a, b.\)
2. The second half of a walk in \(W_a^b\) (which starts from \(a\)) intersects \(P_{a,b'}\) for \(b \neq b'.\)
Let fix In this section, we bound the probability of bad events, as detailed in Definition 5.4. As before, we 5.4 The probabilities of bad events.

\[ P_a \in W_a^b \] and a walk in \( W_b^a \) intersect twice. Note that this is a pair of walks, one from \( a \) and the other from \( b \). The first intersection is in the first half of either of the walks. The walks also end at the same vertex.

Claim 5.5. If all \( P_{a,b} \) sets are non-empty and there is no bad event, then \( \bigcup_{a,b} P_{a,b} \) contains a \( K_{r_2, r_2} \)-minor.

Proof. The \( P_{a,b} \) sets may not form simple paths, and it will be convenient to “clean them up”. Each \( P_{a,b} \) is formed by \( W_a \subseteq W_b^a \) and \( W_b \subseteq W_b^a \) that end at the same vertex. Since there is no Type 3 bad event, \( W_a(\leq \tau) \) is disjoint from \( W_b \) (and vice versa). Therefore (by removing self-intersections and loops), we can construct a simple path from \( a \) to \( b \) with the following (vertex) disjoint contiguous simple paths: \( Q_{a,b} \subseteq W_a(\leq \tau) \), \( P_{a,b} \subseteq W_a(\geq \tau) \cup W_b(\geq \tau) \), and \( Q_{b,a} \subseteq W_b(\leq \tau) \).

In each bullet below, we first make a statement about the disjointness of these various sets. The proof follows immediately. We consider \( a, a' \in A \) and \( b, b' \in B \), where the elements in \( A \) (or \( B \)) might be equal.

- If \( a \neq a' \), \( Q_{a,b} \cap Q_{a',b'} = \emptyset \). If \( b \neq b' \), \( Q_{b,a} \cap Q_{b',a'} = \emptyset \).

Consider the first statement. (Note that we allow \( a = a' \).) Observe that \( Q_{a,b} \subseteq W_a \) and \( Q_{a',b'} \subseteq P_{a',b'} \). So \( W_a \cap P_{a',b'} \neq \emptyset \), implying a Type 1 bad event. The second statement has an analogous proof.

- \( Q_{a,b} \cap Q_{b',a'} = \emptyset \).

If \( a = a', b = b' \), then this holds by the argument in the first paragraph (no Type 3 bad events). Suppose \( a \neq a' \). Then (as before), \( Q_{a,b} \subseteq W_a \) and \( Q_{b',a'} \subseteq P_{a',b'} \). Since no Type 1 bad events occur, \( W_a \cap P_{a',b'} = \emptyset \). The case \( b \neq b' \) is analogous.

- \( Q_{a,b} \cap Q_{b',a'} = \emptyset \).

Wlog, assume \( a \neq a' \). Note that \( \tilde{P}_{a,b} \subseteq W_a(\geq \tau) \cup W_b(\geq \tau) \), where \( W_a \subseteq W_a^b \) and \( W_b \subseteq W_b^a \). If \( W_a(\geq \tau) \cap P_{a',b'} \neq \emptyset \), then \( W_a \cap P_{a',b'} \neq \emptyset \) (a Type 1 bad event). Suppose \( W_b(\geq \tau) \cap P_{a',b'} \neq \emptyset \). If \( b \neq b' \), this is Type 1 bad event. So suppose \( b = b' \), so \( W_b(\geq \tau) \cap P_{a',b} \neq \emptyset \). Since \( W_b \subseteq W_b^a \) (for \( a \neq a' \)), this is Type 2 bad event.

We construct the minor. Let \( C(a) = \bigcup_{b \in B} Q_{a,b} \) and \( C(b) = \bigcup_{a \in A} Q_{b,a} \). Each \( C(a) \), \( C(b) \) forms a connected subgraph. By the disjointness properties of the \( Q_{a,b} \) sets, all the \( C(a) \), \( C(b) \) sets/subgraphs are vertex disjoint. Note that \( \tilde{P}_{a,b} \) is disjoint from all other \( P_{a',b'} \) paths and all the \( C(a) \), \( C(b) \) sets. (We construct \( P_{a,b} \) to be disjoint from \( Q_{a,b} \) and \( Q_{b,a} \) in the first paragraph. Every other \( Q_{a',b'} \) is contained in \( P_{a',b'} \).) Thus, we have disjoint paths from each \( C(a) \) to \( C(b) \), which gives a \( K_{r_2, r_2} \)-minor.

5.4 The probabilities of bad events

In this section, we bound the probability of bad events, as detailed in Definition 5.4. As before, we fix \( s \in S_t \) and condition on \( A \cup B \subseteq R_t \).

We require some technical definitions of random walk probabilities.

Definition 5.6. Let \( \sigma_{s,S,t}(v) \) be the probability of a walk from \( s \) to \( v \) of length \( t \) being \( S \)-returning. (We allow \( \ell \mid t \), and require that the walk encounters \( S \) at every \( j \ell \)-th step, for \( j \leq \lfloor t/\ell \rfloor \).

We use \( \sigma_{s,S,t} \) to denote the vector of these probabilities. More generally, given any distribution vector \( \mathbf{x} \) on \( V \), \( \sigma_{s,S,t} \) denotes the vector of \( S \)-returning walk probabilities at time \( t \).
We stress that this is not a conditional probability. Note that if \( t = 2^i \ell \), then \( \sigma_{s,S,t} = q^{(i)}_{\sigma_{s,S,1}} \).

We show some simple propositions on these vectors. Let \( \mathbb{I}_S \) denote the \( n \times n \) matrix that preserves all coordinates in \( S \) and zeroes out other coordinates.

**Proposition 5.7.** The vector \( \sigma_{x,S,t} \) evolves according to the following recurrence. Firstly, \( \sigma_{x,S,0} = x \). For \( t \geq 1 \) such that \( \ell \mid t \), \( \sigma_{x,S,t} = M\sigma_{x,S,t-1} \). For \( t \geq 1 \) such that \( \ell \nmid t \), \( \sigma_{x,S,t} = \mathbb{I}_S M\sigma_{x,S,t-1} \)

**Proposition 5.8.** For all \( x \) and all \( t \geq 1 \), \( \|\sigma_{x,S,t}\|_{\infty} \leq \|\sigma_{x,S,t-1}\|_{\infty} \).

**Proof.** Since \( M \) is a symmetric random walk matrix, it computes the “new” value at a vertex by averaging the values of the neighbors (and itself). This can never increase the maximum value. Furthermore, \( \mathbb{I}_S \) only zeroes out some coordinates. This proves the proposition. \( \square \)

In what follows, we fix the walk length to \( 2^i \ell \). To reduce clutter, we drop notational dependencies on this length.

**Definition 5.9.** The distribution of \( 2^i \ell \)-length walks from \( u \) is denoted \( W_u \). For any walk \( W, W_u(t) \) denotes the \( t \)th vertex of the walk.

The Boolean predicate \( \rho(W_u) \) is true if \( W_u \) is \( R_i \)-returning.

Recall that \( D_{a,i} \) is the distribution with support \( R_i \), where the probability of \( u \in R_i \) is \( \frac{q^{(i+1)}_{\sigma_{s,R_i},1}(v)}{\|q^{(i+1)}_{\sigma_{s,R_i},1}\|_1} \) (Definition 4.10). Conditioned on \( a \in R_i \), this is precisely the distribution that the elements of the sets \( A, B \) are drawn from. Refer to FindBiclique, where \( A \cup B \) are the destinations of \( 2^{i+1} \ell \) random walks from \( s \). Since \( i \) is fixed, we will simply write this as \( D_a \).

**Claim 5.10.** For any \( F \subseteq V \):

1. \[ \Pr_{a \sim D_a, W_a \sim W_u} [\rho(W_a) \land W_a \cap F \neq \emptyset] \leq 2^i \ell|F|/(n^{\delta(i-1)}\|q^{(i+1)}(R_i,s)\|_1). \]

2. For any \( a \in R_i \),

\[ \Pr_{W_a \sim W_u} [\exists t \geq \tau \mid \rho(W_a) \land W_a(t) \in F] \leq 2^i \ell|F|/n^{\delta(i-2)} \]

**Proof.** We prove the first part. Let \( x \) be the probability vector corresponding to \( D_a \). So \( \|x\|_{\infty} = \|q^{(i+1)}_{\sigma_{s,R_i},1}\|_{\infty}/\|q^{(i+1)}_{\sigma_{s,R_i},1}\|_1 \). By Prop. 5.8, \( \forall t \geq 1 \), \( \|\sigma_{x,R_i,t}\|_{\infty} \leq \|x\|_{\infty} \). sing Claim 4.7, this is at most \( 1/(n^{\delta(i-1)}\|q^{(i+1)}_{\sigma_{s,R_i},1}\|_1) \). We union bound over \( F \) and the walk length.

\[ \Pr_{a \sim D_a, W_a \sim W_u} [\rho(W_a) \land W_a \cap F \neq \emptyset] \leq \sum_{t \leq 2^i \ell, v \in F} \Pr_{a \sim D_a, W_a \sim W_u} [\rho(W_a) \land W_a(t) = v] \]

\[ \leq \sum_{t \leq 2^i \ell, v \in F} \|x\|_{\infty} \leq 2^i \ell|F|/(n^{\delta(i-1)}\|q^{(i+1)}_{\sigma_{s,R_i},1}\|_1) \]

Now for the second part. By the union bound, the probability is bounded above by

\[ \sum_{t \geq 2^{i-1} \ell, u \in F} \Pr_{W_a \sim W_a} [\rho(W_a) \land W_a(t) = u] \leq \sum_{t \geq 2^{i-1} \ell, u \in F} \|\sigma_{a,R_i,t}\|_{\infty} \]

By Prop. 5.8, the infinity norm is bounded above by \( \|\sigma_{a,R_i,2^{i-1} \ell}\|_{\infty} = \|q^{(i-1)}_{\sigma_{s,R_i},a}\|_{\infty} \). By Claim 4.7, the latter is at most \( 1/n^{\delta(i-2)} \). Plugging in (27), we get an upper bound of \( 2^{i-1} \ell|F|/n^{\delta(i-2)} \). \( \square \)
Claim 5.11. For any $a \in R_i$,

$$
\Pr_{b \sim D_s, \omega_a \sim \omega_b, \omega_b \sim \omega_b} \left[ \rho(W_a) \wedge \rho(W_b) \wedge W_a(2^i \ell) = W_b(2^i \ell) \wedge (\exists t_a, t_b, \min(t_a, t_b) \leq \tau, W_a(t_a) = W_b(t_b)) \right] 
\leq 2^{2i \ell^2} / (n^{\delta(2i - 2)} \| q_{[R_i]}^{(i+1)} \|_1)
$$

Proof. Let us write out the main event in English. We fix an arbitrary $a$, and pick $b \sim D_s$. We perform $R_t$-returning walks of length $2^i \ell$ from both $a$ and $b$. We are bounding the probability that the “initial half” (less than $2^{i-1} \ell$ steps) of one of the walks intersects with the other, and subsequently, both walks end at the same vertex.

To that end, let us define two vertices $w_1, w_2$. We want to bound the probability of that both walks first encounter $w_1$, and then end at $w_2$. It is very useful to treat the latter part simply as two walks from $w_1$, where one of them is at least of length $2^{i-1} \ell$. Note that $w_1$ might not be in $R_i$.

Let $Z_{a,t}$ be the random variable denoting the $t$th vertex of a random walk from $a$. Let us also define $R_t$-returning walks with an offset $g$, starting from $w$. Basically, such a walk starts from $w$ (that may not be in $R_i$) and performs $g$ steps to end up in $R_i$. Subsequently, it behaves as an $R_i$-returning walk. Observe that the second parts of the walks are $R_i$-returning walks from $w_1$, with offsets of $\ell - [t_a(\text{mod } \ell)], \ell - [t_b(\text{mod } \ell)]$. Let $Y_{a,t}$ be the random variable denoting the $t$th vertex of an $R_i$-returning walk from $w$, with the offset $\ell - [t(\text{mod } \ell)]$. We use primed versions for independent such variables.

Let us fix values for $t_a, t_b$ such that $\min(t_a, t_b) \leq \tau = 2^{i-1} \ell$. (We will eventually union bound over all such values.) The probability we wish to bound is the following. We use independence of the walks to split the probabilities. There are four independent walks under consideration: one from $a$, one from $b$, and two from $w$.

$$
\sum_{w_1 \in V} \sum_{w_2 \in V} \Pr_{b \sim D_s, \omega_a, \omega_b} \left[ Z_{a,t_a} = w_1 \wedge Z_{b,t_b} = w_1 \wedge Y_{w,1,2^i \ell-t_a} = w_2 \wedge Y_{w,1,2^i \ell-t_b} = w_2 \right] = \sum_{w_1 \in V} \sum_{w_2 \in V} \Pr_{\omega_a} \left[ Z_{a,t_a} = w_1 \right] \Pr_{\omega_b} \left[ Z_{b,t_b} = w_1 \right] \Pr_{\omega_{w_1}} \left[ Y_{w,1,2^i \ell-t_a} = w_2 \right] \Pr_{\omega_{w_1}} \left[ Y_{w,1,2^i \ell-t_b} = w_2 \right]
$$

Consider $\Pr_{b \sim D_s, \omega_b}[Z_{b,t_b} = w_1]$. This is exactly the $w_1$th entry in $\sigma_{x,R_i,t_b}$ where $x$ is the distribution given by $D_s$. By Prop. 5.8, this is at most $\|x\|_\infty$, which is at most $1/(n^{\delta(1-1)} \| q_{[R_i]}^{(i+1)} \|_1)$ (as argued in the second part of the proof of Claim 5.10).

Since $\min(t_a, t_b) \leq \tau$, one of $2^i \ell - t_a, 2^i \ell - t_b$ is at least $2^{i-1} \ell$. Thus, one of $\Pr_{\omega_{w_1}}[Y_{w,1,2^i \ell-t_a} = w_2]$ or $\Pr_{\omega_{w_1}}[Y_{w,1,2^i \ell-t_b} = w_2]$ refers to a walk of length at least $2^{i-1} \ell$. Let us bound $\Pr_{\omega_{w_1}}[Y_{w,1,t} = w_2]$ for $t \geq 2^i \ell$. We can break such a walk into two parts: the first $\ell - [t(\text{mod } \ell)]$ steps lead to some $v \in R_i$, and the second part is an $R_i$-returning walk of length at least $2^i \ell$ from $v$ to $u$. Recall that $p_{x,d}(y)$ is the standard random walk probability of starting from $x$ and ending at $y$ after $d$ steps. For some $t^\prime \geq 2^i \ell$,

$$
\Pr_{\omega_{w_1}}[Y_{w,1,t} = w_2] = \sum_{v \in R_i} p_{w_1, \ell - [t(\text{mod } \ell)]}(v) \sigma_{v,R_i,t^\prime}(w_2) \leq \sum_{v \in R_i} p_{w_1, \ell - [t(\text{mod } \ell)]}(v) \| \sigma_{v,R_i,t^\prime} \|_\infty \leq \sum_{v \in R_i} p_{w_1, \ell - [t(\text{mod } \ell)]}(v) n^{-\delta(1-1)} = n^{-\delta(1-1)}
$$
Plugging these bounds in (28), for fixed $t_a, t_b$, there exists $t \in \{2^i \ell - t_a, 2^i \ell - t_b\}$ such that the probability of the main event is at most

\[
\frac{2^{2i+4} \delta^3 n^{30\delta}}{n^{\delta i/2} \|q^{(i+1)}_{[R_i],a}\|_1}
\]

A union bound over all pairs of $t_a, t_b$ completes the proof.

We now bound the total probability of bad events. Most of the technical work is already done in the previous lemmas; we only need to perform some union bounds.

**Lemma 5.12.** Conditioned on $A \cup B \subseteq R_i$, the total probability of bad events is at most

\[
\frac{2^{2i+4} \delta^3 n^{30\delta}}{n^{\delta i/2} \|q^{(i+1)}_{[R_i],a}\|_1}
\]

**Proof.** We bound the bad events by type. Recall that $\ell = n^{\delta}$. 

**Type 1:** $\exists a, b, c \in A \cup B$, $c \neq a, b$, such that $W_c \cap P_{a,b} \neq \emptyset$.

Fix a choice of $a \in A, b \in B$. Conditioned in $A \cup B \subseteq R_i$, any $c \neq a, b$ is drawn from $\mathcal{D}_s$.

In Claim 5.10, set $F = P_{a,b}$. By the first part of Claim 5.10, the probability that a single walk drawn from $W_c$ is $R_i$-returning and intersects $P_{a,b}$ is at most $2^i \ell (2^i+1) \ell / n^{\delta (i-1)} \|q^{(i+1)}_{[R_i],a}\|_1$. The set $W_c$ consists of at most $r^2 n^\delta (i+18)/2$ such walks. We union bound over all these walks, and all $r^4$ choices of $a, b$, and plug in $\ell = n^{\delta}$ to get an upper bound of

\[
\frac{2^{2i+1} \delta^3 n^{30\delta}}{n^{\delta i/2} \|q^{(i+1)}_{[R_i],a}\|_1}
\]

**Type 2:** $\exists a, b, b'$ (all distinct) such that $\exists W \in W_{a}^{b}$ where $W(\geq \tau) \cap P_{a,b'} \neq \emptyset$. (Or, $\exists a, a' \in A, b \in B$ with analogous conditions.)

Fix $a, b, b'$. Set $F = P_{a,b'}$ in Claim 5.10. By the second part of Claim 5.10, the probability that a single walk from $W_a$ is $R_i$-returning and intersects $F$ at step $\geq \tau$ is at most $2^i \ell (2^i+1) \ell / n^{\delta (i-2)}$. We union bound over all the $r^2 n^\delta (i+18)/2$ walks in $W_a$ and all $r^6$ choices of $a, b, b'$. (We also union bound over choosing $b, b'$ or $a, a'$.) The upper bound is $2^{2i+1} \delta^3 n^{20\delta}/n^{\delta i/2}$.

**Type 3:** $\exists a, b, W_a \in W_{a}^{b}, W_b \in W_{b}^{a}$ such that $W_a, W_b$ end at the same vertex and $\exists t_1, t_2$ such that $\min(t_1, t_2) \leq \tau$ and $W_a(t_1) = W_b(t_2)$.

This case is qualitatively different. We will take a union bound over pairs of walks, and require the stronger bound of Claim 5.11.

Fix $a \in A$. Observe that $b \sim \mathcal{D}_s$. For a single walk $W_a \sim W_a$ and a single walk $W_b \sim W_b$, the probability of a Type 3 bad event is bounded by Claim 5.11. The upper bound is $2^{2i} \ell^2 / (n^{\delta (2i-2)} \|q^{(i+1)}_{[R_i],a}\|_1)$. We union bound over the $r^4 n^\delta (i+18)$ pairs of walks from $a$ and $b$, and then over the $r^4$ choices of $a, b$. The final bound is:

\[
\frac{2^{2i} r^2 \delta^3 n^{30\delta}}{n^{\delta i/2} \|q^{(i+1)}_{[R_i],a}\|_1} = \frac{2^{2i} r^4 n^{30\delta}}{n^{\delta i} \|q^{(i+1)}_{[R_i],a}\|_1}
\]
We complete the proof by taking a union bound over the three types. Note that \( \|q_{[R_i],s}^{(i+1)}\|_1 \leq 1 \), so we can upper bound the probability of each type of bad event by \( \frac{2^{2i+1}r^8n^{30\delta}}{n^{\delta i/2}\|q_{[R_i],s}^{(i+1)}\|_1} \).

\[\square\]

5.5 Proof of Theorem 5.1

**Proof.** Fix \( s \in S_i \). Let \( C \) be the event that \( A \cup B \subseteq R_i \), let \( E \) be the event \( \bigcap_{a,b \in B} P_{a,b} \neq \emptyset \), and let \( F \) be the union of bad events. By Claim 5.5, the probability that \( \text{FindBiclique}(s) \) finds a minor is at least \( \text{Pr}[C] \). We lower bound as follows: \( \text{Pr}[E \cap F \geq \text{Pr}[C] | \text{Pr}[E | C = \text{Pr}[F | C]] \).

Note that \( \text{Pr}[C] = \|q_{[R_i],s}^{(i+1)}\|_1^2 \). By Claim 4.8, \( \|q_{[R_i],s}^{(i+1)}\|_1 \geq n^{-\delta} \), so \( \text{Pr}[C] \geq n^{-2\delta r^2} \).

Lemma 5.3 provides a lower bound for \( \text{Pr}[E | C] \), and Lemma 5.12 provides an upper bound for \( \text{Pr}[F | C] \). We plug these bounds in below.

\[
\text{Pr}[E | C] - \text{Pr}[F | C] \geq \frac{1}{(4n^{2\delta})^{r^2}} - \frac{2^{2i+4}r^8n^{30\delta}}{n^{\delta i/2}\|q_{[R_i],s}^{(i+1)}\|_1} \tag{29}
\]

Observe how the positive term is independent of \( i \), while the negative term decays exponentially in \( i \). This is crucial to argue that for a sufficiently large (constant) \( i \), the lower bound is non-trivial.

When \( i \geq 5r^4 \), \( n^{\delta i/2} \geq n^{25r^4+5r^4/2} \geq n^{25r^4+40\delta} \) (note that, \( r \), the number of vertices in \( H \), is at least 3). By Claim 4.8, \( \|q_{[R_i],s}^{(i+1)}\|_1 \geq n^{-\delta} \). Thus, for sufficiently large \( n \), \( \text{Pr}[F | C] \leq 1/(2(4n^{2\delta})^{r^4}) \).

Putting it all together, the probability of finding a \( K_{r^2,r^2} \)-minor is at least \( n^{-4\delta r^4} \). \( \square \)

6 Local partitioning in the trapped case

Theorem 5.1 tells us that if there are \( \Omega(n^{1-\delta}) \) vertices in strata numbered \( 5r^4 \) and above, then \( \text{FindMinor} \) finds a biclique minor with high probability. We deal with the case when most vertices lie in low strata, i.e., random walks from most vertices are trapped in a very small subset.

We will argue that (almost) all vertices in low strata can be partitioned into “pieces”, such that each piece is a low conductance cut, and (a superset of) each piece can be found by performing random walks in \( G \). If \( \text{FindMinor} \) fails to find a minor, this lemma can be iteratively applied to make \( G \) \( H \)-minor free by removing few edges (this argument is given in §7).

We use \( p_{s,t}(v) \) to denote the probability that at \( t \) length random walk from \( s \) ends at \( v \).

**Lemma 6.1.** Let \( \alpha \geq n^{-\delta/2} \). Consider some subset \( S \subseteq V \) and \( i \in \mathbb{N} \) such that \( \forall s \in S, \|q_{[S],s}^{(i)}\|_2^2 \leq 1/n^{\delta(i-1)} \). Define \( S' \subseteq S \) to be \( \{s | s \in S \text{ and } \|q_{[S],s}^{(i+1)}\|_2^2 \geq 1/n^{\delta i}\} \).

Suppose \( |S'| \geq \alpha n \). Then, there is a subset \( S \subseteq S' \), \( |\tilde{S}| \geq \alpha n/8 \) such that \( \forall s \in \tilde{S} \): there exists a subset \( P_s \subseteq S \) where

- \( E(P_s, S \setminus P_s) \leq 2n^{-\delta i/4} d |P_s| \)
- \( \forall v \in P_s, \exists t \leq 160n^{\delta (i+7)}/\alpha \text{ such that } p_{s,t}(v) \geq \alpha / n^{\delta (2i+14)}. \)

The aim of this section is to prove this lemma. Henceforth, we will assume that \( S, S' \) are as defined in the lemma.

Using the norm bounds, we show that for every vertex \( s \in S' \), there is a large set of destination vertices that are all reached with high probability through random walks of length \( 2^{i+1} \ell \).
Claim 6.2. For every $s \in S'$, there exists a set $U_s \subseteq S$, $|U_s| \geq n^{\delta(i-2)}$, such that $\forall u \in U_s$, $p_{s,2^{i+1}\ell}(u) \geq 1/2 n^{\delta i}$.

Proof. By Prop. 4.2, for any $u \in U$, $q^{(i+1)}_{[S],s}(u) = q^{(i)}_{[S],s} : q^{(i)}_{[S],u}$. By the property of $S$ and Cauchy-Schwartz, $q^{(i+1)}_{[S],s}(u) \leq 1/n^{\delta(i-1)}$.

Since $s \in S'$, $\sum_{u \in S} q^{(i+1)}_{[S],s}(u) \geq 1/n^{\delta i}$. Let us simply define $U_s$ to be the set of vertices $u \in S$ such that $q^{(i+1)}_{[S],s}(u) \geq 1/2 n^{\delta i}$. Note that $p_{s,2^{i+1}\ell}(u) \geq q^{(i+1)}_{[S],s}(u)$.

$$1/n^{\delta i} \leq \sum_{u \in S} q^{(i+1)}_{[S],s}(u)^2 = \sum_{u \in U_s} q^{(i+1)}_{[S],s}(u)^2 + \sum_{u \notin U_s} q^{(i+1)}_{[S],s}(u)^2 \leq |U_s|/n^{2\delta(i-1)} + (1/2 n^{\delta i}) \sum_{u \notin U_s} q^{(i+1)}_{[S],s}(u) \leq |U_s|/n^{2\delta(i-1)} + 1/2 n^{\delta i} \quad (31)$$

We rearrange to bound the size of $U_s$.

6.1 Local partitioning on the projected Markov chain

We define the “projection” of the random walk onto the set $S$. This uses a construction of [KPS13]. We define a Markov chain $M_S$ over the set $S$. We retain all transitions from the original random walk on $G$ that are within $S$, and we denote these by $e^{(1)}_{u,v}$ for every $u \to v$ transition in the random walk on $G$. Additionally, for every $u, v \in S$ and $t \geq 2$, we add a transition $e^{(t)}_{u,v}$. The probability of this transition is equal to the total probability of $t$-length walks in $G$ from $u$ to $v$, where all internal vertices in the walk lie outside $S$.

Since $G$ is irreducible and the stationary mass on $S$ is non-zero, all walks eventually reach $S$. Thus the outgoing transition probabilities from each $v \in M_S$ sum to 1, and hence $M_S$ is a valid Markov chain. Furthermore, by the symmetry of the original random walk, $e^{(t)}_{u,v} = e^{(t)}_{v,u}$. Therefore the transition matrix of $M_S$ remains symmetric, and the stationary distribution is uniform on $S$.

For a transition $e^{(t)}_{u,v}$ in $M_S$, we define the length of this transition to be $t$. For clarity, we use “hops” to denote the length of a walk in $M_S$, and retain “length” for walks in $G$. The length of an $h$ hop random walk in $M_S$ is defined to be the sum of the lengths of the transitions it takes. We note that these ideas come from the work of Kale-Peres-Seshadhri to analyze random walks in noisy expanders [KPS13].

We use $\tau_{s,h}$ to denote the distribution of the $h$-hop walk from $s$, and $\tau_{s,h}(v)$ to denote the corresponding probability of reaching $v$. We use $W_h$ to denote the distribution of $h$-hop walks starting from the uniform distribution in $S$.

We state Kac’s formula (Corollary 24 in Chapter 2 of [AF02], restated).

Lemma 6.3. (Kac’s formula) The expected return time (in $G$) to $S$ of a random walk starting from $S$ is reciprocal of the fractional stationary mass of $S$, ie $n/|S|$.

The following is a direct corollary.

Lemma 6.4. $\mathbb{E}_{W \sim W_h}[\text{length of } W] = hn/|S|$
We will construct Markov Chain, the infinity norm is non-increasing in \( \tau \) number of hops is always at most the length). Since

Proof. Define event \( s' \) as follows. The event \( s' \) occurs when an \( h \)-hop random walk from \( s \) has length \( 2^{i+1} \ell \) and ends at \( v \). Observe that \( p_{s,2^{i+1} \ell}(v) = \sum_{h \leq 2^{i+1} \ell} \Pr[s',v,h] \) (because the number of hops is always at most the length). Since \( \tau_{s,h} \) is a random walk vector in a symmetric Markov Chain, the infinity norm is non-increasing in \( h \). Thus, it suffices to find a subset \( S'' \subseteq S' \), \( |S''| \geq |S'|/2 \) such that \( \forall s \in S'' \), \( \exists v \in S, h \geq n^{\delta}, \Pr[s',v,h] \geq 1/n^{\delta(i+6)} \).

We define \( U_s \) as given in Claim 6.2. For all \( v \in U_s \), by Claim 6.2, \( p_{s,2^{i+1} \ell}(v) \geq 1/2n^{\delta i} \). Therefore, for all \( v \in U_s \),

\[
\sum_{h \geq 2^{i+1} \ell} \Pr[s',v,h] \geq 1/2n^{\delta i} \tag{32}
\]

We will construct \( S'' \) by finding \( s \) where for some \( v \in U_s \), \( \sum_{h \leq n^{\delta}} \Pr[s',v,h] \) is sufficiently small.

For any \( h \),

\[
\frac{1}{|S|} \sum_{s \in S'} \sum_{v \in U_s} \Pr[s',v,h] \leq E_{W \sim W_n} [\text{length of } W] = hn/|S|
\]

Suppose \( h \leq 2^{i+1} \ell/n^{\delta} \). (This is true for all \( h \leq n^{\delta} \).) Then \( \sum_{s \in S'} \sum_{v \in U_s} \Pr[s',v,h] \leq n^{1-4\delta} \), and \( \sum_{h \leq n^{\delta}} \sum_{s \in S'} \sum_{v \in U_s} \Pr[s',v,h] \leq n^{1-3\delta} \).

We rearrange to get

\[
\sum_{s \in S'} \sum_{v \in U_s} \sum_{h \leq n^{\delta}} \Pr[s',v,h] \leq n^{1-3\delta}
\]

By the Markov bound, there is a set \( S'' \subseteq S' \), \( |S''| \geq |S'|/2 \) such that for all \( s \in S'' \), \( \sum_{v \in U_s} \sum_{h \leq n^{\delta}} \Pr[s',v,h] \leq 2n^{1-3\delta}/|S''| \). By averaging, \( \forall s \in S'' \), \( \exists v \in U_s \), such that \( \sum_{h \leq n^{\delta}} \Pr[s',v,h] \leq 2n^{1-3\delta}/(|S''| \cdot |U_s|) \). By the assumptions of Lemma 6.1, \( |S'| \geq \alpha n \geq n^{1-\delta/2} \). Claim 6.2 bounds \( |U_s| \geq n^{\delta(i-2)} \). Plugging these in,

\[
\sum_{h \leq n^{\delta}} \Pr[s',v,h] \leq \frac{2n^{1-3\delta}}{n^{1-\delta/2} n^{\delta(i-2)}} = \frac{2}{n^{\delta(i+1/2)}} \tag{33}
\]

Subtracting this bound from (32), \( \sum_{h \in [n^{\delta}, 2^{i+1} \ell]} \Pr[s',v,h] \geq 1/4n^{\delta i} \). By averaging, for some \( h \in [n^{\delta}, 2^{i+1} \ell] \), \( \Pr[s',v,h] \geq 1/(2^{i+3} n^{\delta i} \ell) \geq 1/n^{\delta(i+6)} \). This completes the proof. \[ \square \]

We perform local partitioning on \( M_S \), starting with arbitrary \( s \in S'' \). We apply the Lovász-Simonovits curve technique. (The definitions are originally from [LS90]. Refer to Lecture 7 of Spielman’s notes [Spi] as well as Section 2 in Spielman-Teng [ST12].) This requires a series of definitions.

- Ordering of states at time \( t \): At time \( t \), let us order the vertices in \( M_S \) as \( v_1^{(t)}, v_2^{(t)}, \ldots \) such that \( \tau_{s,i}(v_1^{(t)}) \geq \tau_{s,i}(v_2^{(t)}) \ldots \), breaking ties by vertex id.
The LS curve $h_t$: We define a function $h_t : [0, |S|] \to [0, 1]$ as follows. For every $k \in [|S|]$, set $h_t(k) = \sum_{j \leq k} \tau_{s,t}(v_j^{(t)}) - 1/|S|$ (Set $h_t(0) = 0$). For every $x \in (k, k+1)$, we linearly interpolate to construct $h(x)$. Alternately, $h_t(x) = \max_{\bar{v} \in [0,1]^{|S|}, \|\bar{v}\|_1 = x} \sum_{v \in S} \tau_{s,t}(v) - 1/n |\bar{v}|$.

- Level sets: For $k \in [0, |S|]$, we define the $(k,t)$-level set, $L_{k,t}$ to be $\{v_1^{(t)}, v_2^{(t)}, \ldots, v_k^{(t)}\}$. The minimum probability of $L_{k,t}$ denotes $\tau_{s,t}(v_k^{(t)})$.
- Conductance: for some $T \subseteq S$ we define the conductance of $T$ in $M_S$ to be

$$\Phi(T) = \frac{\sum_{v \in T} \tau_{u,1}(v)}{\min(|T|, |S \setminus T|)}$$

The main lemma of Lovász-Simonovits is the following (Lemma 1.4 of [LS90]).

**Lemma 6.6.** For all $k$ and all $t$,

$$h_t(k) \leq \frac{1}{2} [h_{t-1}(k - 2 \min(k, n-k) \Phi(L_{k,t})) + h_{t-1}(k + 2 \min(k, n-k) \Phi(L_{k,t}))]$$

The typical use of the Lovász-Simonovitz technique is to argue about rapid mixing when all conductances (or conductances of sufficiently large sets) are lower bounded. We consider a scenario in which only sets with minimum probability at least (say) $p$ have high conductance. In this case, we can guarantee that the largest probability will converge to $p$.

**Lemma 6.7.** Suppose the following holds. For all $t'$, if the minimum probability of $L_{k,t'}$ is at least $1/10 n^\delta(i+6)$, then $\Phi(L_{k,t'}) \geq n^{-\delta/4}$. Then, $\forall x \in [0, n]$, $h_t(x) \leq \sqrt{x}(1 - n^{-\delta/2}/4)^t + x/10 n^\delta(i+6)$.

**Proof.** Notice that it suffices to show this claim for integral values of $x$ since $h_t$ is concave. To begin with, note that if $x = k \geq n^\delta(i+6)$, then the RHS is at least 1. Thus the bound is trivially true. Let us assume that $k < n^\delta(i+6) < n/2$. We proceed by induction over $t$ and split into two cases based on the conductance of level sets.

Suppose $k$ is such that $\Phi(L_{k,t}) \geq n^{-\delta/4}$. By Lemma 6.6 and concavity of $h$, we have the following at $x = k$:

$$h_t(k) \leq \frac{1}{2} \left( h_{t-1}(k(1 - 2n^{-\delta/4})) + h_{t-1}(k(1 + 2n^{-\delta/4})) \right)$$

$$\leq \frac{1}{2} \left( \sqrt{k(1 - 2n^{-\delta/4})(1 - n^{-\delta/2}/4)^{t-1}} + \sqrt{k(1 + 2n^{-\delta/4})(1 - n^{-\delta/2}/4)^{t-1}} + \frac{2k}{10 n^\delta(i+6)} \right)$$

$$\leq \frac{1}{2} \left( \sqrt{k(1 - 2n^{-\delta/4})} (1 - n^{-\delta/4}) + \sqrt{k(1 + 2n^{-\delta/4})} (1 - n^{-\delta/4}) + \frac{2k}{10 n^\delta(i+6)} \right)$$

$$\leq \sqrt{k(1 - n^{-\delta/2}/2)^t} + k/n^\delta(i+6)$$

For the last inequality we use the bound $(\sqrt{1+x} + \sqrt{1-x})/2 \leq 1 - x^2/8$.

Now, consider the case where $k$ is such that $\Phi(L_{k,t}) \leq n^{-\delta/4}$. By assumption, it must be that $L_{k,t'}$ must have minimum probability less than $1/10 n^\delta(i+6)$. Let $k'$ be the largest integer less than
k such that $\Phi(L_{k'}) \geq n^{-\delta/4}$. By the previous case, $h_t(k') \leq \sqrt{k'}(1 - n^{-\delta/2}/2)^t + k/n^\delta(i+6)$. Using this and the concavity of $h_t$, we get

$$h_t(k) \leq h_t(k') + (k - k')/10n^\delta(i+6)$$

$$\leq \sqrt{k'}(1 - n^{-\delta/2}/2)^t + k'/10n^\delta(i+6) + (k - k')/10n^\delta(i+6)$$

$$\leq \sqrt{k}(1 - n^{-\delta/2}/2)^t + k/10n^\delta(i+6)$$

(38) (39) (40)

\[ \square \]

6.2 Proof of Lemma 6.1

Proof. Define $S''$ as given in Lemma 6.5. For any $s \in S''$, $\|\tau_{s,n^\delta}\|_\infty \geq 1/n^\delta(i+6)$. By the definition of the LS curve, $h_{n^\delta}(1) \geq 1/n^\delta(i+6)$. Suppose (for contradiction’s sake) all level sets for $t \leq n^\delta$ with minimum probability at least $1/10n^\delta(i+6)$ have conductance at least $n^{-\delta/4}$. By Lemma 6.7, $h_{n^\delta}(1) \leq (1 - n^{-\delta/2}/4)n^3 + 1/10n^\delta(i+6) < 1/n^\delta(i+6)$. This contradicts the bound obtained by Lemma 6.5.

Thus, for every $s \in S''$, there exists some level set for $t_s \leq n^\delta$ with minimum probability at least $1/10n^\delta(i+6)$ and conductance $< n^{-\delta/4}$. Let us call this level set $P_s$. We also use the fact that $|P_s| \leq |S|/2$. By the construction of $M_S$, we have,

$$\Phi(P_s) \geq \sum_{x \in P_s} \sum_{y \in S \setminus P_s} \frac{\tau_{x,y}(y)}{\min(|P_s|, |S \setminus P_s|)} = \frac{E(P_s, S \setminus P_s)}{2d|P_s|}$$

The first inequality follows because we restrict the numerator to length one transitions in the Markov Chain $M_S$ (which correspond to edges in $G$). Rearranging, we get $E(P_s, S \setminus P_s) \leq n^{-\delta/4}(2d|P_s|)$.

For all $s \in S''$ and $v \in P_s$, $\tau_{s,n^\delta}(v) \geq 1/10n^\delta(i+6)$. Set $L = 160n^\delta(i+7)/\alpha$. Let $\tilde{S}$ be the subset of $S''$ such that $\forall s \in \tilde{S}$, $P_s$ is such that $\forall v \in P_s$, $\sum_{l \leq L} p_{s,l}(v) \geq 1/20n^\delta(i+6)$. By averaging, $\exists l \leq L$ such that $p_{s,l}(v) \geq \alpha/n^{\delta(2i+14)}$.

We have seen that $\tilde{S}$ satisfies the two desired properties: for all $s \in \tilde{S}$, $E(P_s, S \setminus P_s) \leq 2n^{-\delta/4}d|P_s|/\alpha$ and for all $v \in P_s$, $\exists t \leq 160n^\delta(i+7)$ such that $p_{s,t}(v) \geq \alpha/n^{\delta(2i+14)}$. It only remains to prove a lower bound on $|S'' \setminus \tilde{S}|$.

Consider any $s \in S'' \setminus \tilde{S}$. There exists some $v_s \in P_s$ such that $\tau_{s,n^\delta}(v_s) \geq 1/10n^\delta(i+6)$ but $\sum_{l \leq L} p_{s,l}(v_s) < 1/20n^\delta(i+6)$. Let us use $\tilde{\tau}_{s,l}(v_s)$ to denote the probability of reaching $v_s$ from $s$ in an $l$-length walk that makes $n^\delta$ hops. Observe that

$$\tau_{s,n^\delta}(v_s) = \sum_{l \geq n^\delta} \tilde{\tau}_{s,l}(v_s) = \sum_{l=0}^{L} \tilde{\tau}_{s,l}(v_s) + \sum_{l > L} \tilde{\tau}_{s,l}(v_s) \leq \sum_{l=0}^{L} p_{s,l}(v_s) + \sum_{l > L} \tilde{\tau}_{s,l}(v_s)$$

$$< 1/20n^\delta(i+6) + \sum_{l > L} \tilde{\tau}_{s,l}(v_s)$$

(41) (42)

The last inequality follows from the fact that $s \in S'' \setminus \tilde{S}$, and hence $\sum_{l \leq L} p_{s,l}(v_s) < 1/20n^\delta(i+6)$. Since $\tau_{s,n^\delta}(v_s) \geq 1/10n^\delta(i+6)$, the above calculation shows that $\sum_{l > L} \tilde{\tau}_{s,l}(v_s) > 1/20n^\delta(i+6)$. Thus,

$$\frac{1}{|S|} \sum_{s \in S'' \setminus \tilde{S}} \sum_{l > L} \tilde{\tau}_{s,l}(v_s)L > |S'' \setminus \tilde{S}| \cdot L = 160\alpha^{-1}n^\delta(i+7) \cdot |S'' \setminus \tilde{S}| = \frac{8n^\delta|S'' \setminus \tilde{S}|}{\alpha|\tilde{S}|}$$

(43)
By Lemma 6.4,
\[ \frac{1}{|S|} \sum_{s \in S'' \setminus \tilde{S}} \sum_{l > L} \hat{p}_{s,l}(v_s)L \leq E_{W \sim \mathcal{W}}[\text{length of } W] = \frac{n^{1+\delta}}{|S|} \] (44)
Combining the above, \(|S'' \setminus \tilde{S}| \leq \alpha n/8\). By Lemma 6.5, \(|S''| \geq |S'|/2 \geq \alpha n/2\), yielding the bound \(|\tilde{S}| \geq \alpha n/4\).

7 Wrapping it all up: the proof of Theorem 3.1

We have all the tools required to complete the proof of Theorem 3.1. Our aim is to show that if \(\text{FindMinor}(G, \varepsilon, H)\) outputs an \(H\)-minor with probability < 2/3, then \(G\) is \(\varepsilon\)-close to being \(H\)-minor free. Henceforth in this section, we will simply assume the “if” condition.

The following decomposition procedure is used by the proof. We set parameter \(\alpha = \varepsilon/(50r^4 \log n)\).

Decompose\((G)\)

1. Initialize \(S = V\) and \(\mathcal{P} = \emptyset\).
2. For \(i = 1, \ldots, 5r^4\):
   (a) Assign \(S' := \{ s \in S : \|q_{[S],s}^{(i+1)}\|_2^2 \geq 1/n^{\delta_i} \}\)
   (b) While \(|S'| \geq \alpha n\):
      i. Choose arbitrary \(s \in S''\), and let \(P_s\) be as in Lemma 6.1.
      ii. Add \(P_s\) to \(\mathcal{P}\) and assign \(S := S \setminus P_s\)
      iii. Assign \(S' := \{ s \in S : \|q_{[S],s}^{(i+1)}\|_2^2 \geq 1/n^{\delta_i} \}\)
   (c) Assign \(S := S \setminus S'\)
   (d) Assign \(X_i := S'\)
3. Let \(X = \bigcup_i X_i\).
4. Output the partition \(\mathcal{P}, X, S\)

The procedure Decompose repeatedly employs Lemma 6.1 for values of \(i \leq 5r^4\). In the \(i\)th iteration, eventually \(|S'|\) becomes too small for Lemma 6.1. Then, \(S'\) is moved (from \(S\)) to an “excess” set \(X_i\), and the next iteration begins. Decompose ends with a partition \(\mathcal{P}, X, S\) where each set in \(\mathcal{P}\) is a low conductance cut, \(X\) is fairly small, and FindBiclique succeeds with high probability on every vertex in \(S\).

This is formalized in the next lemma.

**Lemma 7.1.** Assume \(\varepsilon > \varepsilon_{\text{CUTOFF}}\). Suppose \(\text{FindMinor}(G, \varepsilon, H)\) outputs an \(H\)-minor with probability < 2/3. Then, the output of Decompose satisfies the following conditions.

- \(|X| \leq \varepsilon n/10\).
- \(|S| \leq \varepsilon n/10\).
- \(\forall P_s \in \mathcal{P}, v \in P_s, \exists t \leq 160n^{6\delta r^4}/\alpha \) such that \(p_{s,t}(v) \geq \frac{\alpha}{n^{11\delta r^4}}\).
- There are at most \(\varepsilon n/10\) edges that go between different \(P_s\) sets.

**Proof.** Consider the \(X_i\)’s formed by Decompose. Each of these has size at most \(\alpha n = \varepsilon n/50r^4 \log n\), and there are at most \(5r^4\) of these. Clearly, their union has size at most \(\varepsilon n/10\).

The third condition holds directly from Lemma 6.1. Consider the number of edges that go between \(P_s\) and the rest of \(S\), when \(P_s\) was constructed (in Decompose). By Lemma 6.1 again, the
number of these edges is at most $2n^{-\delta/4}|d(P)|/\alpha = 40r^4(\log n)\varepsilon^{-1}n^{-\delta/4}|d(P)|$. Note that $\varepsilon > \varepsilon_{\text{cutoff}}$. For sufficiently small constant $\delta$, the number of edges between $P_s$ and $S \setminus P_s$ (at the time of removal) is at most $\varepsilon|P_s|/10$. The total number of such edges is at most $\varepsilon n/10$ (since $P_s$ are all disjoint).

Suppose, for contradiction’s sake, that $|S| > \varepsilon n/10$. Consider the stratification process with $R_0 = S$. By construction of $S$, $\forall s \in S$, $||q_s^{[5r^4+1]}|| \leq 1/n^{5\delta r^4}$. Thus, all of these vertices will lie in strata numbered $5r^4$ or above. Since $\varepsilon > \varepsilon_{\text{cutoff}}$, by Lemma 4.9, at most $\varepsilon n/\log n$ vertices are in strata numbered more than $1/\delta + 3$. By Theorem 5.1, for at least $\varepsilon n/10 - \varepsilon n/\log n \geq \varepsilon n/20$ vertices, the probability that the paths discovered by $\text{FindBiclique}(s)$ contain an $K_{2,2}$-minor is at least $n^{-4\delta r^4}$. Since a $K_{2,2}$ minor contains an $H$-minor, the algorithm (in this situation) will succeed in finding an $H$-minor.

All in all, this implies that the probability that a single call to $\text{FindBiclique}$ finds an $H$ minor is at least $n^{-5\delta r^4}$. Since $\text{FindMinor}$ makes $n^{20\delta r^4}$ calls to $\text{FindBiclique}$, an $H$-minor is found with probability at least $5/6$. This is a contradiction, and we conclude that $|S| \leq \varepsilon n/10$.

And now, we can prove the correctness guarantee of $\text{FindMinor}$.

**Claim 7.2.** Suppose $\text{FindMinor}(G, \varepsilon, H)$ outputs an $H$-minor with probability $< 2/3$. Then $G$ is $\varepsilon$-close to being $H$-minor free.

**Proof.** If $\varepsilon \leq \varepsilon_{\text{cutoff}}$, then $\text{FindMinor}$ runs an exact procedure. So the claim is clearly true. Henceforth, assume $\varepsilon > \varepsilon_{\text{cutoff}}$. Apply Lemma 7.1 to partition $V$ into $P, X, S$.

Call $s \in V$ bad, if there is a corresponding $P_s \in P$ and $P_s$ induces an $H$-minor. By Lemma 7.1, for all $v \in P$, $\exists t \leq 160n^{6\delta r^4}/\alpha$ such that $p_{s,t}(v) \geq \alpha/n^{11\delta r^4}$. Note that $160n^{6\delta r^4}/\alpha \leq n^{7\delta r^4}$ and $\alpha/n^{11\delta r^4} \geq n^{-12\delta r^4}$. Also, $|P_s| \leq 160(n^{6\delta r^4}/\alpha) \times (n^{11\delta r^4}/\alpha) \leq n^{18\delta r^4}$. Note that $\text{LocalSearch}(s)$ performs walks of all lengths up to $n^{7\delta r^4}$, and performs $n^{30\delta r^4}$ walks of each length. For any $v \in P_s$, the probability that $\text{LocalSearch}(s)$ does not add $v$ to $B$ (the set of “discovered” vertices in $\text{LocalSearch}(s)$) is at most $(1 - n^{-12\delta r^4})^{n^{30\delta r^4}} \leq 1/n^2$. Taking a union bound over $P_s$, the probability that $P_s$ is not contained in $B$ is at most $1/n$. Consequently, for bad $s$, $\text{LocalSearch}(s)$ outputs an $H$-minor with probability $> 1 - 1/n$.

Suppose there are more than $n^{1-30\delta r^4}$ bad vertices. The probability that a uar $s \in V$ is bad is at least $n^{-30\delta r^4}$. Since $\text{FindMinor}(G, \varepsilon, H)$ invokes $\text{LocalSearch} n^{35\delta r^4}$ times, the probability that $\text{LocalSearch}(s)$ is invoked for a bad vertex is at least $1 - 1/n$. Thus, $\text{FindMinor}(G, \varepsilon, H)$ outputs an $H$-minor with probability $> 1 - 2/n$, contradicting the claim assumption.

We conclude that there are at most $n^{1-30\delta r^4}$ bad vertices. Each $P_s$ has at most $n^{18\delta r^4}$ vertices, and $|\bigcup s \text{ bad } P_s| \leq n^{1-12\delta r^4} \leq \varepsilon n/10$.

We can make $G$-minor free by deleting all edges incident to $X$, all edges incident to $S$, all edges incident to vertices in any bad $P_s$ sets, and all edges between $P_s$ sets. By Lemma 7.1 and the bound given above, the total number of edges deleted is at most $4\varepsilon dn/10 < \varepsilon dn$.

Finally, we bound the running time.

**Claim 7.3.** The running time of $\text{FindMinor}(G, \varepsilon, H)$ is $dn^{1/2+O(\delta r^4)} + d\varepsilon^{-2\exp(2/\delta)}/\delta$.

**Proof.** If $\varepsilon < \varepsilon_{\text{cutoff}}$, then the running time is simply $O(n^2)$. Since $\varepsilon < n^{-\delta/\exp(2/\delta)}$, this can be expressed as $\varepsilon^{-2\exp(2/\delta)}/\delta$. 

27
Assume $\varepsilon \geq \varepsilon_{\text{CUTOFF}}$. The total number of vertices encountered by all the LocalSearch calls is $n^{O(\delta r^4)}$. There is an extra $d$ factor to determine all incident edges, through vertex queries. Thus, the total running time is $dn^{O(\delta r^4)}$, because of the quadratic overhead of KKR. Consider a single iteration for the main loop of FindBiclique. First, FindBiclique performs $2r^2$ random walks of length $2^{i+1}n^{5\delta}$, and then for each of these, FindPath performs $n^{\delta i/2+9\delta}2^i n^{5\delta}$. Hence, the total steps (and thus, queries) in all walks performed by a single call to FindBiclique is

$$
\sum_{i=5r^4}^{1/\delta+3} \left( 2r^2 2^{i+1}n^{5\delta} + 2r^2 n^{\delta i/2+9\delta}2^i n^{5\delta} \right) = r^2 n^{1/2+O(\delta)}.
$$

While this is the total number of vertices encountered, we note that the calls made to KKR($F,H$) are for much smaller graphs. The output of find path has size $O(2^{1/\delta}n^{5\delta})$, and the subgraph $F$ constructed has at most $O(2^{1/\delta}n^{5\delta})$ vertices. We incur an extra $d$ factor to determine the induced subgraph, through vertex queries. Thus, the time for each call to KKR($F,H$) is $n^{O(\delta)}$. There are $n^{O(\delta r^4)}$ calls to FindBiclique, and we can bound the total running time by $dn^{1/2+O(\delta r^4)}$. \hfill \Box
